Giovannoni Logistics Project Phase 1 Energy Use Summary

Summary of Energy Use During Construction		(Annually)
Construction vehicle fuel	115,596	gallons (gasoline, diesel)
Construction equipment fuel	25,955	gallons (diesel)
Total construction fuel	141,550	gallons (gasoline, diesel)
Construction office electricity	10,025	kilowatt hours

Summary of Energy Use During Operations		(Annually)
Operational Vehicle Fuel	573,717	gallons (gasoline, diesel)
Operational TRU Fuel (Cold Storage)	583	gallons (diesel)
Operational Natural Gas (Cold Storage)	4,040,000	kilo-British Thermal Units
Operational Natural Gas (Dry Storage)	3,690,000	kilo-British Thermal Units
Operational Electricity (Cold Storage)	10,944,476	kilowatt hours
Operational Electricity (Dry Storage)	4,264,476	kilowatt hours

Construction Vehicle Fuel Calculations

California Air Resource Board (ARB). 2020. EMFAC2017 Web Database. Website: https://arb.ca.gov/emfac/2017/. Accessed July 22, 2021.

VMT = Vehicle Miles Traveled
FE = Fuel Economy

EMFAC2017 (v1.0.2) Emission Rates
Region Type: County
Region: NAPA
Calendar Year: 2022
Season: Annual
Vehicle Classification: EMFAC2007 Categories
Units: miles/day for VMT, trips/day for Trips, g/mile for RUNEX, PMBW and PMTW, g/trip for STREX, HTSK and RUNLS, g/vehicle/day for IDLEX, RESTL and DIURN. Note 'day' in the unit is operation day.

Giovannoni Logistics Project Phase 2 Energy Use Summary

Summary of Energy Use During Construction		(Annually)
Construction vehicle fuel	221,932	gallons (gasoline, diesel)
Construction equipment fuel	25,956	gallons (diesel)
Total construction fuel	247,888	gallons (gasoline, diesel)
Construction office electricity	10,127	kilowatt hours

Summary of Energy Use During Operations		(Annually)
Operational Vehicle Fuel	678,793	gallons (gasoline, diesel)
Operational TRU Fuel (Cold Storage)	721	gallons (diesel)
Operational Natural Gas (Cold Storage)	5,020,000	kilo-British Thermal Units
Operational Natural Gas (Dry Storage)	4,570,000	kilo-British Thermal Units
Operational Electricity (Cold Storage)	13,550,926	kilowatt hours
Operational Electricity (Dry Storage)	5,300,926	kilowatt hours

Construction Vehicle Fuel Calculations

Model Assumptions and Methodology

The BAAQMD has developed a set of guidelines[1] that recommends using the American Meteorological Society and Environmental Protection Agency Regulatory Model (AERMOD) air dispersion model to estimate emission concentrations for use in identifying the cancer risk and hazard index associated with sensitive receptor exposure to project construction emissions. The following modeling parameters were employed using AERMOD, Version 21112, to estimate diesel particulate matter (DPM) emission concentrations that were used in the associated cancer risk and hazard calculations.

AERMOD Modeling Parameters

1. Sensitive receptors (e.g., schools, daycare facilities, hospitals, care facilities, residences) in the immediate project vicinity are represented in the model with discrete cartesian receptors. The closest sensitive receptors to the project site, in all directions, include the following:
   - One single-family residence approximately 200 feet southwest of the project site (834 Green Island Road).
   - One single-family residence approximately 315 feet southwest of the project site (850 Green Island Road).
   - One single-family residence approximately 250 feet southwest of the project site (876 Green Island Road).
   - One single-family residence approximately 220 feet southwest of the project site (1190 Green Island Road).
   - One single-family residence approximately 690 feet southwest of the project site (1300 Green Island Road).
   - One single-family residence approximately 1,045 feet southwest of the project site (unknown street address along Green Island Road).
   - One single-family residence approximately 3,150 feet west of the project site (1808 Green Island Road).
   - Two single-family residences approximately 2,510 feet south of the project site (300 & 310 Hess Road).
   - Single-family residential neighborhoods beginning approximately 3,870 feet south of the project site.
   - Calvary Baptist Christian Academy approximately 4,040 feet south of the project site.
   - Multi-family residences approximately 3,690 feet southeast of the project site (110-800 Reliant Way).
   - Several single-family residences approximately 2,180 feet southeast of the project site (along Watson Lane).

[1] Bay Area Air Quality Management District (BAAQMD). 2020. BAAQMD Health Risk Assessment Modeling Protocol. December. Website: https://www.baaqmd.gov/~/media/files/ab617-community-health/facility-risk-reduction/documents/baaqmd_hra_modeling_protocol_august_2020-pdf.pdf?la=en. Accessed April 13, 2021.

- One single-family residence approximately 1,790 feet east of the project site (unknown street address along Paoli Loop Road).
- One single-family residence approximately 1,860 feet northeast of the project site (5775 Broadway).

2. A nested cartesian grid was placed in AERMOD with the following spacing parameters:
   - 20 meters spacing within the project site and up to 200 meters from the project site;
   - 50 meters spacing between 200 and 500 meters from the project site; and
   - 250 meters spacing between 500 and 2,000 meters from the project site.
   - 500 meters spacing between 2,000 and 5,000 meters from the project site.
3. AERMOD's non-default regulatory dispersion option was selected. Among the dispersion control options available, the Fast All Sources option was selected.
4. The Urban dispersion coefficient was used as greater than 50 percent of the surrounding three kilometers is developed.
5. The UTM coordinates used to initially locate the project site are 10 S, 564,796 meters easting, 4,227,956 meters northing.
6. Emissions were characterized in the model using various area sources to represent different activities. The following describes the emission sources utilized in the model for each model scenario.

   Project Scenario 1 (Phase 1 Construction)
   - On-site construction activities are represented with one polygon area source across the entire Phase 1 project site.
   - Off-site construction hauling and vendor truck operation for Phase 1 is represented with line volume sources along Green Island Road, Devlin Road (existing), and Highway 29.

   Project Scenario 2 (Phase 1 Operation & Phase 2 Construction)
   - On-site construction activities are represented with one polygon area source across the entire Phase 2 project site.
   - Off-site construction hauling and vendor truck operation for Phase 2 is represented with line volume sources along Green Island Road, Devlin Road (existing and new), and Highway 29.
   - On-site operational activities are represented with one polygon area source across the entire Phase 1 project site.
   - Off-site operational trucking fleet operation for Phase 1 is represented with line volume sources along Green Island Road, Devlin Road (existing and new), and Highway 29.
   - Off-site operational rail operation for Phase 1 is represented with one line volume source along the California Northern Railroad railway that connects to the project site.

   Project Scenario 3 (Phase 1 & Phase 2 Operation)
   - On-site operational activities are represented with one polygon area source across the entire project site.

- Off-site operational trucking fleet operation for the entire project is represented with line volume sources along Green Island Road, Devlin Road (existing and new), and Highway 29.

Off-site emissions were adjusted to only account for off-site emissions that would occur within 1,000 feet of the project site (see Off-Site $PM_{2.5}$ Exhaust Adjustment Sheet of this Appendix). As shown therein, each line volume source was assigned an emission rate equal to its proportion of the off-site emissions based on the length of the respective line volume source divided by the combined length of all line volume source(s).

7. Meteorological data from the Napa County Airport Air Monitoring Station, Station ID 93227. This station was selected as it is the closest monitoring station to the project site, and it resembles physical site characteristics and elevation generally representative of the project site. The Napa County Airport Air Monitoring Station provides preprocessed meteorological data for 2009. The model used all years of available meteorological data.

Estimation of Diesel Particulate Matter Emissions

Construction Diesel Particulate Matter (DPM) emissions—represented as $PM_{2.5}$ exhaust—were estimated using CalEEMod, Version 2020.4.0. Construction of Phase 1 of the project is expected to begin in January 2022 and conclude 10 months later. Construction of Phase 2 of the project is expected to begin immediately following completion of Phase 1 construction and conclude 10 months later in 2023. Construction emissions for both project phases were assumed to be distributed over the project area with a working schedule of 8 hours per day, 5 days per week.

Due to the phased nature of the project, the HRA analyzes the proposed project's Phase 1 construction DPM emissions for the first year, Phase 1 operational and Phase 2 construction DPM emissions for the second year, and Phase 1 and 2 operational DPM emissions for the remainder of the 30-year exposure duration, consistent with the BAAQMD's Health Risk Assessment Guidelines.[2] The HRA also analyzes the proposed project's Phase 1 construction DPM emissions for the first year, Phase 1 operational and Phase 2 construction DPM emissions for the second year, and Phase 1 and 2 operational DPM emissions of school receptor exposure at the Calvary Baptist Christian Academy and the proposed project's operational DPM emission concentrations for the remainder of the 13-year exposure duration for a K-12 school, consistent with the BAAQMD's Health Risk Assessment Guidelines.

To reduce NO_X and GHG emissions to less than significant levels, the proposed project would be required to implement MM AIR-2d, which would require that the trucking fleet utilized during operation of both Project Phases is 2014 model year or newer. As a result, all "Operational DPM" emission estimates displayed below in Table 1 incorporate implementation of MM AIR-2d. Because the proposed project could accommodate the construction and operation of 2.4 million square feet of cold storage space and the subsequent operation of TRUs in addition to truck and passenger vehicle activities, the HRA herein analyzes the cold storage project scenario as a conservative assessment.

Table 1: Project DPM Construction Emissions

Scenario	On-site DPM Project Site (tons/year)	Off-site DPM Road/Rail Segments (tons/year)	Total Local DPM Emissions (tons/year)
Impact Scenario 1 (Construction of Project Phase 1)			
Phase 1 Construction DPM	0.08101	0.03016	0.11117
Impact Scenario 2 (Operation of Project Phase 1 and Construction of Project Phase 2)			
Phase 1 Operational DPM[1]	0.16679	0.72038	0.88717
Phase 2 Construction DPM	0.07044	0.02092	0.09136
Impact Scenario 3 (Operation of Project Phase 1 and Operation of Project Phase 2)			
Phase 1 Operational DPM[1]	0.16679	0.72038	0.88717
Phase 2 Operational DPM[1]	0.19362	0.83642	1.03004

[1] Includes implementation of Mitigation Measure AIR-4 (2014 model year or newer trucking fleet).
Source: CalEEMod Output and Construction Health Risk Assessment Calculations; see Appendix B.

To assess potential health risk impacts to off-site sensitive receptors, the American Meteorological Society/Environmental Protection Agency Regulatory Model (AERMOD) air dispersion model was used to estimate the DPM emission concentrations at nearby sensitive receptors within 1,000 feet of the project site.

Estimation of Cancer Risks

The BAAQMD has developed a set of guidelines for estimating cancer risks resulting from exposure to toxic air contaminants (TAC).[3,4] These guidelines require the use of Hotspots Analysis and Reporting Program (HARP2) software to identify the cancer risk associated with DPM generated during construction activities. The HARP2 risk scenario inputs used to calculate cancer risk during project construction are as follows:

Residential Receptors

1. Analysis Type: Cancer Risk
2. Receptor Type: Individual Resident
3. Scenario 1 Exposure Duration: User Defined (Tier 2) – 1 Year, 3rd Trimester Start Age
4. Scenario 2 Exposure Duration: User Defined (Tier 2) – 1 Year, Age 1 Start Age
5. Scenario 3 Exposure Duration: User Defined (Tier 2) – 28 Years, Age 2 Start Age
6. Intake Rate Percentile: Risk Management Policy (RMP) - *Inhalation Only*
7. Selected: “Apply Molecular Weight Adjustment Factor” factor

[3] Bay Area Air Quality Management District (BAAQMD). 2016. BAAQMD Air Toxics NSR Program Health Risk Assessment Guidelines. December. Website: https://www.baaqmd.gov/~/media/files/planning-and-research/permit-modeling/hra_guidelines_12_7_2016_clean-pdf.pdf?la=en. Accessed June 22, 2021.

[4] Bay Area Air Quality Management District (BAAQMD). 2020. BAAQMD Health Risk Assessment Modeling Protocol. December. Website: https://www.baaqmd.gov/~/media/files/ab617-community-health/facility-risk-reduction/documents/baaqmd_hra_modeling_protocol-pdf.pdf?la=en. Accessed June 22, 2021.

8. Pathways to Evaluate: Inhalation Only
9. Selected: “Apply fraction of time at residence to age bins less than 16 years”
10. Selected: “Apply fraction of time at residence to age bins greater than or equal to 16 years”
11. Selected: “Use Tier 2 breathing rates (L/kg-day)” factor
12. Selected: “Use Tier 2 fraction of time at residence” factor

School Receptors (Calvary Baptist Christian Academy, K-12)

1. Analysis Type: Cancer Risk
2. Receptor Type: Individual Resident
3. Scenario 1 Exposure Duration: User Defined (Tier 2) – 1 Year, Age 5 Start Age
4. Scenario 2 Exposure Duration: User Defined (Tier 2) – 1 Year, Age 6 Start Age
5. Scenario 3 Exposure Duration: User Defined (Tier 2) – 11 Years, Age 7 Start Age
6. Intake Rate Percentile: 95th (High End)
7. Selected: “Apply Molecular Weight Adjustment Factor” factor
8. Pathways to Evaluate: Inhalation Only
9. Selected: “Use adjustment factors”
10. Exposure frequency (days/year): 180 days
11. Selected: “Use Tier 2 breathing rates (L/kg-day)” factor

Estimation of Non-Cancer Chronic Hazards

An evaluation of the potential non-cancer effects of chronic chemical exposures was also conducted. Adverse health effects are evaluated by comparing the annual receptor concentration of each chemical compound with the appropriate reference exposure limit. Available reference exposure limits promulgated by the California Office of Environmental Health Hazard Assessment (OEHHA) were considered in the assessment.

Risk characterization for non-cancer health hazards from toxic air contaminants (TAC) is expressed as a Hazard Index. The Hazard Index is a ratio of the predicted concentration of the project’s emissions to a concentration considered acceptable to public health professionals, termed the reference exposure limit. The Hazard Index assumes that chronic sub-threshold exposures adversely affect a specific organ or organ system (toxicological endpoint). For each discrete chemical exposure, target organs presented in regulatory guidance were used. To calculate the Hazard Index, each chemical concentration or dose is divided by the appropriate toxicity reference exposure level. For compounds affecting the same toxicological endpoint, this ratio is summed. Where the total equals or exceeds 1, a health hazard is presumed to exist. For purposes of this assessment, the TAC of concern is DPM for which the OEHHA has defined a reference exposure limit for DPM of 5 $\mu g/m^3$. The principal toxicological endpoint assumed in this assessment was through inhalation.

Cancer Risk and Non-Cancer Chronic Hazard Summary

Table 2 summarizes the cancer risk and hazard index results for the maximally impacted receptors (MIR) under each impact scenario. For Impact Scenario 1, the residential MIR represents a single-family residence approximately 1,860 feet northeast of the project site and the school MIR represents the Calvary Baptist Christian Academy. As previously noted, the proposed project would be required to implement MM AIR-2d, requiring the use of a 2014 model year or newer trucking fleet during project

operation. As such, cancer risk and chronic non-cancer hazards shown in Table 2 account for the implementation of MM AIR-2d.

Table 2: Estimated Cancer Risks and Chronic Non-Cancer Hazards (Proposed Project)

Impact Scenario	Cancer Risk[1] (risk per million)	Chronic Non-Cancer Hazard Index[2]	TAC Concentration[3] (µg/m^3)
Residential MIR Impact (Cold Storage Scenario)			
Scenario 1 (Phase 1 Construction)	0.44	<0.01	<0.01
Scenario 2 (Phase 2 Construction, Phase 1 Operation)	1.44	<0.01	0.01
Scenario 3 (Phase 1, Phase 2 Operation)	0.22	0.01	0.04
Total (30 Year Duration)	*2.10*	*0.01*	*0.05*
Thresholds of Significance	**10**	**1**	**0.3**
Exceeds Individual Source Threshold?	**No**	**No**	**No**
School MIR Impact (Cold Storage Scenario)			
Scenario 1 (Phase 1 Construction)	0.01	<0.01	<0.01
Scenario 2 (Phase 2 Construction, Phase 1 Operation)	0.03	<0.01	<0.01
Scenario 3 (Phase 1, Phase 2 Operation)	0.20	<0.01	<0.01
Total (30 Year Duration)	*0.24*	*<0.01*	*<0.01*
Thresholds of Significance	**10**	**1**	**0.3**
Exceeds Individual Source Threshold?	**No**	**No**	**No**

Notes:
[1] Cancer risk is identified by multiplying the risk sum from HARP2 by 1,000,000.
[2] Chronic non-cancer hazard index was estimated by dividing the annual DPM concentration (as $PM_{2.5}$ exhaust) by the DPM reference exposure level of 5 µg/m^3.
[3] TAC concentration taken from AERMOD is always at the MIR identified from the project air dispersion models. The residential MIR was located at 38.20613°N -122.25739°E and the school MIR was identified as the Calvary Baptist Christian Academy.
REL = reference exposure level
MIR = maximally impacted sensitive receptor
µg/m^3 = micrograms per cubic meter
Emissions Source: Appendix B.

Cumulative Health Risk Assessment

The BAAQMD recommends assessing the potential cumulative impacts from sources of TACs within 1,000 feet of a project. For a project-level analysis, BAAQMD provides several tools for use in screening potential sources of TACs. The BAAQMD-provided tools used to assess the potential cumulative impacts from TACs are described below:

- **Health Risks for Local Roadways.** The BAAQMD pre-calculated concentrations and the associated potential cancer risks and $PM_{2.5}$ concentration increases for each county within their jurisdiction for roadways that carry at least 30,000 average daily trips. For certain areas, the BAAQMD also includes local roadways that meet BAAQMD's "major roadway" criteria of 10,000 vehicles or 1,000 trucks per day. The latest available screening tool is in the form of a Geographic Information System (GIS) raster file.

- **Freeway Screening Analysis Tool**. The BAAQMD prepared a GIS tool that contains pre-estimated cancer risk and $PM_{2.5}$ concentration increases for highways within the Bay Area. The closest highway to the identified MIR is Highway 29, as close as 600 feet east of the project site.

- **Stationary Source Risk and Hazard Screening Tools**. The BAAQMD prepared a web-based tool[5] with the location of permitted stationary sources. For each emissions source, the BAAQMD provides conservative estimates of cancer risk and $PM_{2.5}$ concentrations. Based on information from the GIS tool, four BAAQMD-permitted stationary sources exist within 1,000 feet of the project site.

- **Rail Screening Tools.** The BAAQMD prepared GIS tools that contains estimated cancer risks and $PM_{2.5}$ concentrations from railroad operations at any point within the Air Basin. The closest rail line to the project site is operated by California Northern Railroad, which will connect directly to Building A during operation of Phase 1 of the proposed project.

A cumulative Health Risk Assessment (HRA) was performed that examined the cumulative impacts of the project's construction emissions and sources of TAC emissions within 1,000 feet of the project site.

The cumulative health risk results, including health risks from the existing stationary source, are summarized during project construction in Table 3. Cumulative health risk results shown therein are representative of the health risks to the residential MIR, which would experience the highest concentration of pollutants.

[5] Bay Area Air Quality Management District (BAAQMD). 2018. Permitted Stationary Sources Risk and Hazards. Permitted Stationary Sources Risk and Hazards. Website: https://baaqmd.maps.arcgis.com/apps/webappviewer/index.html?id=2387ae674013413f987b1071715daa65. Accessed April 16, 2021.

Table 3: Summary of the Cumulative Health Impacts at the MIR during Construction

Source	Source Type	Distance from MIR[1] (feet)	Cancer Risk (per million)	Chronic HI	$PM_{2.5}$ Concentration ($\mu g/m^3$)
Project					
Residential MIR	Diesel Construction Equipment, Trucking Fleets, and Passenger Vehicles	1,860	2.10	0.01	0.05
Existing Stationary Sources (BAAQMD Facility Number)[2]					
California Stonecraft Facility ID 24284	Polyester Resin Operation	1,455	ND	<0.01	ND

Total Offsite	**8.36E-01**

Note: To represent onsite passenger vehicle and truck mobile source emissions, associated offsite emission totals were used with a travel distance of 0.5 mile. For passenger vehicles, offsite emissions were multipled by a factor of 0.5/8.12 to identify onsite emissions. For trucks, offsite emissions were multiplied by a factor of 0.5/32.8 to identify onsite emissions.

Off-Site AERMOD Input Adjustments

Roadway Segment	Length (Miles)	Proportion of Total	$PM_{2.5}$ (Exhaust) Emission Rate (g/sec)
Devlin Road (Existing & New)	1.0	45.07%	**1.439E-04**
Green Island Road	0.7	31.46%	**1.004E-04**
Highway 29	0.5	23.47%	**7.493E-05**
Totals	*2.1*	*100.00%*	*3.192E-04*

Notes:

[1] Conversion factor of 453.592 grams/pound was used to convert daily emissions expressed in pounds to daily emissions expressed in grams.

[2] Off-site emissions used in the AERMOD air dispersion model were reduced to account for the proportion of emissions occurring within 1,000 feet of the project site.

Off-Site Roadway Activity	Total Travel Distances per Trip	Adjusted for 1,000 ft
Passenger Vehicles	8.12 Miles	2.33%
Trucking Fleet	32.8 Miles	0.58%

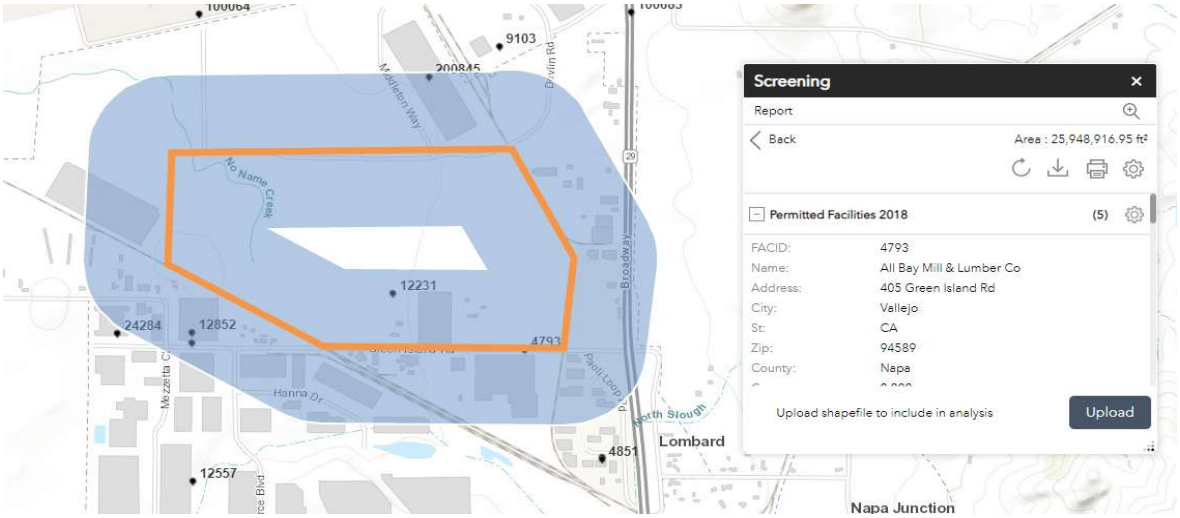
Mitigation Applied	Mitigation Description
MM AIR-2c	Low VOC coatings and paints, electric landscaping equipment
MM AIR-2d	2014 Model Year or newer trucks

Exhaust $PM_{2.5}$ AERMOD Inputs

Annual Hours	**8,760.00**	
On-Site Emissions	**387.24**	**pounds**
	175,648.69	**grams**
	2.005E+01	**grams/hours**
	5.570E-03	**grams/sec**
Off-Site Emissions	**916.60**	**pounds**
(Passenger Vehicles)	**415,762.43**	**grams**
	4.75E+01	**grams/hour**
	1.32E-02	**grams/sec**
Off-Site Emissions	**141.11**	**pounds**
(Trucks)	**64,006.72**	**grams**
	7.31E+00	**grams/hour**
	2.03E-03	**grams/sec**

Existing Stationary Sources within 1,000 Feet of the Project

Lat, Long Project Site: 38.198968°, -122.265359°



Permitted Stationary Sources within 1,000 feet of the Project Site:

1 Facility ID 24284 California Stonecraft, 1111 Green Island Road
2 Facility ID 12852 William Kreysler & Assoc Inc, 501 Green Island Road
3 Facility ID 14432 City of American Canyon / Accounts Paybale, Commerce Blvd & Green Island Road
4 Facility ID 4793 All Bay Mill & Lumber Co, 405 Green Island Road
5 Facility ID 200845 Ikea, 1 Middleton Way

Note: Facility ID 12231's location is misrepresented on the image above. This facility is further to the south, greater than 1,000 feet from the Project Site.

Dispersion Options

Titles

C:\Lakes\AERMOD View\54600001 Giovannoni Logistics_Scenario 1\546000

Dispersion Options

- ☐ Regulatory Default
- ■ Non-Default Options

- ■ Elevated Terrain
- ☐ No Stack-Tip Downwash (NOSTD)
- ☐ Run in Screening Mode
- ☐ Conversion of NOx to NO2 (OLM or PVMRM)
- ☐ No Checks for Non-Sequential Met Data
- ■ Fast All Sources (FASTALL)
- ☐ Fast Area Sources (FASTAREA)
- ☐ Optimized Area Source Plume Depletion
- ☐ Gas Deposition

BETA Options:

- ☐ Capped and Horizontal Stack Releases
- ☐ Adjusted Friction Velocity (u*) in AERMET (ADJ_U*)
- ☐ Low Wind Options

- ☐ SCIM (Sampled Chronological Input Model)
- ☐ Ignore Urban Night / Daytime Transition (NOURBTRAN)

Dispersion Coefficient

Urban

Population:
Name (Optional):
Roughness Length:

Output Type

- ■ Concentration
- ☐ Total Deposition (Dry & Wet)
- ☐ Dry Deposition
- ☐ Wet Deposition

Plume Depletion

- ☐ Dry Removal
- ☐ Wet Removal

Output Warnings

- ☐ No Output Warnings
- ☐ Non-fatal Warnings for Non-sequential Met Data

Pollutant / Averaging Time / Terrain Options

Pollutant Type

PM2.5

Averaging Time Options

Hours ☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 6 ☐ 8 ☐ 12 ☐ 24

☐ Month ■ Period ☐ Annual

Exponential Decay

☐ Yes ■ No

Terrain Height Options

☐ Flat ■ Elevated

SO: Meters
RE: Meters
TG: Meters

Flagpole Receptors

■ Yes ☐ No

Default Height = 1.50 m

Dispersion Options

Titles

C:\Lakes\AERMOD View\54600001 Giovannoni Logistics_Scenario 1\546000

Dispersion Options

- ☐ Regulatory Default
- ■ Non-Default Options

- ■ Elevated Terrain
- ☐ No Stack-Tip Downwash (NOSTD)
- ☐ Run in Screening Mode
- ☐ Conversion of NOx to NO2 (OLM or PVMRM)
- ☐ No Checks for Non-Sequential Met Data
- ■ Fast All Sources (FASTALL)
- ☐ Fast Area Sources (FASTAREA)
- ☐ Optimized Area Source Plume Depletion
- ☐ Gas Deposition

BETA Options:

- ☐ Capped and Horizontal Stack Releases
- ☐ Adjusted Friction Velocity (u*) in AERMET (ADJ_U*)
- ☐ Low Wind Options

- ☐ SCIM (Sampled Chronological Input Model)
- ☐ Ignore Urban Night / Daytime Transition (NOURBTRAN)

Dispersion Coefficient

Urban

Population:
Name (Optional):
Roughness Length:

Output Type

- ■ Concentration
- ☐ Total Deposition (Dry & Wet)
- ☐ Dry Deposition
- ☐ Wet Deposition

Plume Depletion

- ☐ Dry Removal
- ☐ Wet Removal

Output Warnings

- ☐ No Output Warnings
- ☐ Non-fatal Warnings for Non-sequential Met Data

Pollutant / Averaging Time / Terrain Options

Pollutant Type

PM2.5

Averaging Time Options

Hours: ☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 6 ☐ 8 ☐ 12 ☐ 24

- ☐ Month
- ■ Period
- ☐ Annual

Exponential Decay

- ☐ Yes
- ■ No

Terrain Height Options

- ☐ Flat
- ■ Elevated

SO: Meters
RE: Meters
TG: Meters

Flagpole Receptors

- ■ Yes
- ☐ No

Default Height = 1.50 m

Format Type: Default AERMET format

Wind Speed

☐ Wind Speeds are Vector Mean (Not Scalar Means)

Wind Direction

Rotation Adjustment [deg]:

Potential Temperature Profile

Base Elevation above MSL (for Primary Met Tower): 4.30 [m]

Meteorological Station Data

Stations	Station No.	Year	X Coordinate [m]	Y Coordinate [m]	Station Name
Surface		2009			
Upper Air		2009			

Data Period

Data Period to Process

Start Date: 1/1/2009 Start Hour: 1 End Date: 1/2/2014 End Hour: 24

Wind Speed Categories

Stability Category	Wind Speed [m/s]	Stability Category	Wind Speed [m/s]
A	1.54	D	8.23
B	3.09	E	10.8
C	5.14	F	No Upper Bound

This report should be cited as: Huffman-Broadway Group, Inc. 2021. *Biological Resources Report, Giovannoni Logistics Center, American Canyon, California.* San Rafael, California. 52 pp. plus attachments. Prepared for Buzz Oates Construction, Inc., Sacramento, California. May 2021.

1.0 INTRODUCTION

On behalf of Buzz Oates Construction, Inc., Huffman-Broadway Group, Inc. (HBG) has prepared a Biological Resources Report for the Giovannoni Logistics Center Project in the City of American Canyon, California. The approximately 207.8-acre Giovannoni Logistics Center Project (Project Site), also referred to as the Study Area, is located in the northwestern portion of the City of American Canyon, Napa County, California. It is expected that this Biological Resources Report will be used in decision-making with respect to the documentation necessary for the project pursuant to the California Environmental Quality Act (CEQA).

The applicant, Buzz Oates Construction, Inc., is proposing to develop an approximately 2.4 million square foot logistics center and a wetland preserve as open space on approximately 199.5 acres out of the 207.8-acre Project Site. The Devlin Road and Vine Trail Extension Project is currently being developed by the City of American Canyon on the remaining 8.3 acres of the 207.8-acres Project Site. . The applicant has developed site design-level plans for the Giovannoni Logistics Center Project on approximately 113.6 acres of the Project Site. These site-design level plans include development on the approximately 68.8 acre area east of the Devlin Road extension and wetland mitigation plans on an approximately 44.8 acre Wetland Preserve (together referred to herein as the "Project"). The development on the 68.8 areas will support two high cube warehouse buildings totaling 1,069,904 squarefeet. Buildings A would be rail-served by the adjacent Napa Branch Line. Each building would provide docks, grade level roll up doors, and trailer parking stalls. The facility would be enclosed with a secure perimeter and access would be restricted to authorized users. The approximately 44.8 acre wetland preserve will be used to offset wetland impacts associated with the Project, and additional wetland impacts that may occur in the future as part of the possible development of a second phase of the project (referred to herein as the "Phase 2"). If built out, Phase 2 is anticipated to encompass the approximately 85.9-acre area west of Devlin Road and is conceptually proposed to develop the remaining 1.3 million square feet of high cube warehouse space. This Phase 2 project, if constructed, would commence sometime after the proposed Project is completed.

Accordingly, the City of American Canyon's environmental review process pursuant to CEQA will evaluate the proposed project east of Devlin Road with a Project Specific Level of analysis and the second phase west of Devlin Road at a Program Level. The analysis for the proposed Project is independent from the Giovannoni Logistics Center Project Phase 2 (referred to herein as "Phase 2"). When and if Phase 2 moves forward, an addendum to the EIR will need to be conducted and Phase 2 will be re-evaluated based on the specifics and any new environmental or CEQA issues that will need to be assessed.

The objective of this study was to provide a determination of the potential for the Study Area (the entire 207.8-acre Project Site) to support sensitive habitats as defined by state or federal regulation and/or pursuant to the California Environmental Quality Act (CEQA) or for the Study Area to support special status species of flora and fauna. This evaluation also includes an

evaluation to determine whether the proposed construction would result in impacts to sensitive habitats or special status species, recommends mitigation measures necessary to mitigate impacts to levels of insignificance as defined by CEQA, and identifies needs for regulatory permits from state and federal agencies.

HBG's analysis included a review of pertinent literature on habitat characteristics of the site, including species of plants and animals expected to utilize the Project Site and a review of planning documents referencing ecological aspects of the site. These documents included previously prepared biological studies pertaining to the site, including an aquatic resources delineation prepared by Monk & Associates (2016) and surveys for federally listed vernal pool brachiopods conducted by LSA Associates (2016) and Monk & Associates (2017). HBG's work included a Habitat Assessment for the federally listed threatened California red-legged frog prepared by Dr. Mark Jennings, and rare plant surveys, currently underway, by Dr. Brent Helm during the 2021 flowering season.

Also relevant to the biological evaluation were Biological Resource Reports prepared by Monk & Associates for two separate Initial Study/Mitigated Negative Declarations prepared by the City of American Canyon for projects with shared elements to the subject project. These include Biological Resource Reports for the Devlin Road and Vine Trail Extension Project (Monk & Associates 2018) (currently being constructed by the City of American Canyon on 8.3 acres of the Giovannoni Project Site) and the Green Island Road Reconstruction and Widening Project (Monk & Associates 2019).. HBG's work also included an updated review of the California Natural Diversity Data Base (CNDDB) to determine if populations of endangered, threatened, or rare species have occurred on the site historically or are currently known to exist in the project vicinity and included additional field surveys of the site conducted by HBG biologists between December 2020 and April 2021. Additional field reviews will be conducted during the spring and summer of 2021 for the purpose of completing rare plant surveys within the Study Area.

2.0 PROPOSED PROJECT

2.1 Project Location

The 207.8-acre Project Site is located in the northwestern portion of the City of American Canyon, Napa County, California. A regional location map for the Project Site is shown in Figure 1 and the area in the vicinity of the site is shown in Figure 2. The semi-rectangular Project Site is bounded by industrial development in the Green Island Business Park to the west, the Napa Logistics Project and Devlin Road to the north, the Napa Branch Line of the Southern Pacific Railroad to the east, and Green Island Road, a stone supply business, and a wine distribution warehouse to the south. State Highway 29 is located just to the east of the site and the Napa River is less than one mile to the west.

Figure 3 shows the location of the Project Site on the Cuttings Wharf, California, United States Geological Survey 7.5-minute topographic quadrangles, Township 4 North, Range 4 West, Sections 13 and 14 (Latitude 38° 11' 50" North; Longitude 122° 15' 36" West). An aerial image of the Project Site with the US Army Corps of Engineers (USACE) verified wetlands is provided on Figure 4.

2.2 Project Description

2.2.1 Land Use Activities and Designations

The 207.8-acre Project Site is currently undeveloped land and is the largest undeveloped site in the City of American Canyon. The Project Site has sat vacant for decades with the City of American Canyon annexing the property into the City in 2005. The Project Site gently slopes from east to west with an elevation ranging from 35 feet to 50 feet above mean sea level. The West Napa Fault bisects the Project Site in a northwest/southeast direction. The Project Site is designated "Industrial" by the City of American Canyon General Plan and zoned "General Industrial" and is within the boundaries of the Napa County Airport Land Use Compatibility Plan.

The City of American Canyon is currently constructing an extension of Devlin Road bisecting the Project Site[1]. The Devlin Road and Vine Trail Extension project extends approximately 2,800 linear feet from Green Island Road to a completed segment of Devlin Road within the Napa Logistics Park, closing a gap in the City's roadway network. The extension is contemplated by the City of American Canyon General Plan Circulation Element as an Industrial Collector. The extended Devlin Road will be a two-lane roadway with a walking trail, box culvert, and bioretention cells. An extension of the Napa Valley Vine Trail is a component of the Devlin Road extension. Construction of the Devlin Road and Vine Trail Extension project began in the spring of 2021with completion anticipated by the end of 2021..

[1] The Devlin Road extension will encompass approximately 8.3-acres of the 207.8-acre Project Site.

An additional related but separate project by the City of American Canyon is the Green Island Road Reconstruction and Widening Project. Green Island Road would be widened and a new Green Island Road/Devlin Road intersection with turn lanes would be constructed. Anticipated start of construction is 2022.

2.2.2 Proposed Project

The applicant, Buzz Oates Construction, Inc., is proposing to develop an approximately 2.4 million square foot logistics center and a wetland preserve as dedicated open space on approximately 199.5 acres out of the 207.8-acre Project Site. In conjunction with the proposed Project, the City of American Canyon is currently constructing an extension of Devlin Road that will encompass approximately 8.3-acres of the 207.8-acre overall Project Site.
The applicant has developed site design-level plans on the approximately 68.8 acre area east of the Devlin Road extension and wetland mitigation plans on an approximately 44.8 acre Wetland Preserve for a 113.6 acre Project. These site design-level plans for 68.8-acre the portion of the site east of Devlin Road along with the approximately 44.8-acre Wetland Preserve are shown in Figure 5. Building A will have 36' in clearance height and provide 601,383 ground square feet (GSF). Building A will be rail-served by the adjacent Napa Branch Line and equipped with 126 dock positions, 4 grade level roll up doors, 215 trailer parking stalls 12'x55', and 432 vehicle stalls. Building B will have 36' in clearance height and provide 468,521 GSF. Building B will be equipped with 100 dock positions, 4 grade level roll up doors, 148 trailer parking stalls 12'x55', and 442 vehicle stalls. The facility would be enclosed with a secure perimeter and access would be restricted to authorized users.

A Phase 2 project, anticipated on the 85.9-acre area west of Devlin Road, is conceptually proposed for the remaining 1.3 million square feet of high cube warehouse. This Phase 2 project would commence sometime after the proposed Project is completed. The conceptual plan for development area of this Phase 2 in the portion of the site west of Devlin Road is shown in Figure 6. If and when Phase 2 is pursued, work would commence once the proposed Project is completed. Accordingly, the environmental review process conducted by the City of American Canyon pursuant to CEQA will evaluate the proposed Project at a Project Specific level of analysis and Phase 2 at a Program level.

Driveway access to the proposed Project and Phase 2 would be taken from Devlin Road and Green Island Road.

A summary of land uses for the entire Project Site is shown in Table 1.

Table 1. Land Uses for 207.8-acres Project Site			
Phase / Land Use	**Acres**	**Building / Square Feet**	**End Use / Characteristics**
Project (Site Design Level Plans)	68.8	A / 601,383	High Cube Warehouse / 36 feet clear height
		B / 468,521	High Cube Warehouse / 36 feet clear height
	44.8	NA	Wetland Preserve: Will be used to fully mitigate for wetland impacts associated with the Project and to fully, or in part, mitigate for wetland impacts associated with Phase 2.
Phase 2 (Program Level)	85.9	1.3 million	High Cube Warehouse
Devlin Road Extension	8.3	NA	Implemented by City of American Canyon
Total	**207.8**	**2.4 million**	**NA**
Note: Acreage and square footage calculations sourced from CBG Civil Engineers.			

As part of the Project, an approximately 44.8-Acre Wetland Preserve fronting the northern boundary will be preserved, and the preservation site will be used to create approximately 0.992-acre of wetlands (2:1 ratio) to offset wetland impacts associated with the Project, and an additional approximately 3.7-acres of wetlands (1:1 ratio) will be created to offset wetland impacts that may occur in the future as part of Phase 2, assuming Phase 2 is built out. The Conceptual Wetland Mitigation Plan and associated map for the general location of mitigation wetlands in relation to the Project Site and existing wetlands is discussed in detail in Section 5. The Wetland Preserve would create a contiguous open space area with the adjoining 37-acre Napa Logistics Park Wetland Preserve. Figure 5 shows the plans for site-design level development of the proposed Project east of Devlin Road; conceptual plans for future development of Phase 2 west of Devlin Road are shown on Figure 6. An approximately 44.8-acre Wetland Preserve will protect existing seasonal wetlands and vernal pools, protect foraging habitat for raptors, and support established wetlands to offset wetland impacts associated with the Project and Phase 2.

The proposed Project and Phase 2 requires a Use Permit, Tentative Parcel Map, Design Permits, and a Lot Line Adjustment from the City of American Canyon.

3.0 REGULATORY BACKGROUND

The following is a description of federal, state, and local environmental laws and policies that are relevant to the California Environmental Quality Act (CEQA) review process.

3.1 Federal Regulations

Clean Water Act-Section 404

The U.S. Army Corps of Engineers (USACE or Corps) regulates discharges of dredged or fill material into Waters of the United States under Section 404 of the Clean Water Act (CWA). "Discharge of fill material" is defined as the addition of fill material into Waters of the U.S., including but not limited to the following: placement of fill that is necessary for the construction of any structure, or impoundment requiring rock, sand, dirt, or other material for its construction; site-development fills for recreational, industrial, commercial, residential, and other uses; causeways or road fills; and fill for intake and outfall pipes and sub-aqueous utility lines (33 C.F.R. §328.2(f)). In addition, Section 401 of the CWA (33 U.S.C. 1341) requires any applicant for a federal license or permit to conduct any activity that may result in a discharge of a pollutant into Waters of the United States to obtain a certification that the discharge will comply with the applicable effluent limitations and water quality standards.

The USACE and the U.S. Environmental Protection Agency (US EPA) are responsible for implementing the Section 404 program. Section 404(a) authorizes the Corps to issue permits, after notice and opportunity for comment, for discharges of dredged or fill material into waters of United States (WOTUS). Section 404(b) requires that the Corps issue permits in compliance with EPA guidelines, which are known as the Section 404(b)(1) Guidelines. Specifically, the Section 404(b) (1) guidelines require that the Corps only authorize the "least environmentally damaging practicable alternative" (LEDPA) and include all practicable measures to avoid and minimize impacts to the aquatic ecosystem. The guidelines also prohibit discharges that would cause significant degradation of the aquatic environment or violate state water quality standards.

Waters of the U.S. include both wetlands and "other waters of the U.S." Wetlands and other waters of the U.S. are described by US EPA and Corps regulations (40 CFR § 230.3(s) and 33 CFR § 328.3(a), respectively). US EPA and the Corps define wetlands as "…those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions" (US EPA regulations at 40 CFR § 230.3(t); Corps' regulations at 33 CFR § 328.3(b)). Both natural and manmade wetlands and other waters (not vegetated by a dominance of rooted emergent vegetation) are subject to regulation. Waters of the U.S. include a range of wet environments such as lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, and wet meadows.

The geographic extent of wetlands is defined by the collective presence of a dominance of wetland vegetation, wetland hydrology conditions, and wetland soil conditions as determined following the Corps' 1987 Wetlands Delineation Manual (1987 Manual); the Corps' 2008 Regional Supplement to Corps of Engineers Wetland Delineation Manual: Arid West, Version 2.0 (Arid West Regional Supplement); and supporting guidance documents. The geographic extent of other waters of the U.S. is defined by an ordinary high-water mark (OHWM) in non-tidal waters (33 CFR. §328.3(e)) and by the High Tide Line within tidal waters (33 CFR. §328.3(d)). The OHWM is defined by the Corps as "that line on shore established by the fluctuations of water and indicated by physical character of the soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas" (33 C.F.R. §328.3(e)). Tidal waters are also under the jurisdiction of the Corps. The landward limits of jurisdiction in tidal waters extend to the high tide line…"or, when adjacent non-tidal waters of the United States are present, to the limits of jurisdiction for such non-tidal waters" (33 C.F.R.§328.4(b)) High tide is further defined to include the line reached by spring high tides and other high tides that occur with periodic frequency (33 C.F.R.§328.3(d)).

SWANCC and Rapanos. In the U.S. Supreme Court decision *Solid Waste Agency of Northern Cook County v. United States Army Corps of Engineers (SWANCC), No. 99-1178 (2001),* some isolated wetlands may be excluded from the Corps' Section 404 jurisdiction because they are (1) non-tidal, (2) non-navigable, (3) not hydrologically connected to navigable waters or adjacent to such waters, and (4) not subject to foreign or interstate commerce. Subsequent to SWANCC, the U.S. Supreme Court decided on *Rapanos v. United States* and *Carabell v. United States*, 126 U.S. 2208 (2006) (herein referred to as Rapanos) which resulted in 2007, guidance was given to US EPA regions and Corps districts to implement the Supreme Court's decision which addresses the jurisdiction over waters of the U.S. under the Clean Water Act. The Rapanos guidance requires the Corps to conduct detailed analysis of the functions and values of wetlands and other waters of the U.S. potentially onsite and in some cases offsite, to determine if there is a nexus to traditional navigable waters and to evaluate the significance of the nexus to the traditional navigable water. Neither the Court nor the recently-issued guidance draw a clear line with respect to the geographic reach of jurisdiction, particularly in drainages where flows are ephemeral and where wetlands are adjacent to but not directly abutting relatively permanent water.

Navigable Waters Protection Rule. In 2020, the Trump Administration obtained approval of the Navigable Waters Protection Rule (NWPR) that altered the reach of the nation's Clean Water Act. The NWPR has four categories of jurisdictional waters and twelve categories of excluded waters/features. There is no standalone interstate waters category and no case-specific significant nexus analysis. Key changes were made for defining tributary, adjacent wetland, ditches, lakes, ponds, and impoundments. New definitions for defining typical year versus normal, perennial, intermittent, ephemeral, snowpack, and ditches. No change was made to the definition of wetlands or the methodology for defining wetlands. Under the NWPR, WOTUS

includes 1) territorial seas and traditional navigable waters; 2) tributaries; 3) lakes and ponds, and impoundments of jurisdictional waters; and 4) adjacent wetlands.

Clean Water Act-NPDES Requirements

In 1972, the Clean Water Act was amended to provide that the discharge of pollutants to waters of the United States from any point source is unlawful unless the discharge is in compliance with a National Pollution Discharge Elimination System (NPDES) permit. The 1987 amendments established a framework for regulating municipal, industrial, and construction-related storm water discharges under the NPDES Program. On November 16, 1990, the US EPA published final regulations that establish storm water permit application requirements for specified categories of industries. The regulations provide that discharges of storm water from construction projects that encompass one or more acres of soil disturbance are effectively prohibited unless the discharge is in compliance with an NPDES Permit.

The California State Water Resource Control Board has developed a general construction storm water permit to implement the requirements for the federal NPDES permit. The permit requires submittal of a Notice of Intent to comply, fees, and the implementation of a Storm Water Pollution Prevention Plan that specifies Best Management Practices (BMPs) that will prevent construction pollutants from entering storm water and keep products of erosion from migrating off-site into downstream receiving waters. The Construction General Permit includes post-construction requirements that site design provide no increase in overall site runoff or the concentration of drainage pollutants and requires implementation of Low Impact Development ("LID") design features. The Construction General Permit is implemented and enforced by California's nine Regional Water Quality Control Boards.

The State Regional Water Quality Control Boards (SWQCB) have also adopted requirements for NPDES storm water permits for medium and large municipalities, and the State Water Resources Control Board has adopted a General Permit for the discharge of storm water from small municipal storm sewer systems. This General Permit requires projects to develop and implement a post-construction Storm Water Management Plan (SWMP) to reduce the discharge of pollutants to the maximum extent practicable.

Federal Endangered Species Act

The United States Congress passed the Federal Endangered Species Act (FESA) in 1973 to protect those species that are endangered or threatened with extinction. The FESA is intended to operate in conjunction with the National Environmental Policy Act (NEPA) to help protect the ecosystems upon which endangered and threatened species depend. The FESA establishes an official listing process for plants and animals considered to be in danger of extinction, requires development of specific plans of action for the recovery of listed species, and restricts activities perceived to harm or kill listed species or affect critical habitat (16 USC 1532, 1536).

The FESA prohibits the "take" of endangered or threatened wildlife species. "Take" is defined as harassing, harming (including significantly modifying or degrading habitat), pursuing, hunting,

shooting, wounding, killing, trapping, capturing, or collecting wildlife species, or any attempt to engage in such conduct (16 USC 1532, 50 CFR 17.3). Taking can result in civil or criminal penalties. Federal regulation 50 CFR 17.3 further defines the term "harm" in the take definition to mean any act that actually kills or injures a federally listed species, including significant habitat modification or degradation. Additionally, FESA prohibits the destruction or adverse modification of designated critical habitat. In the Service's regulations at 50 CFR 402.2, destruction or adverse modification is defined as a "direct or indirect alteration that appreciably diminishes the value of critical habitat for both the survival and recovery of a listed species.

The ESA also requires federal agencies to ensure that their actions do not jeopardize the continued existence of listed species or adversely modify critical habitat (16 USC 1536). Therefore, the ESA is invoked when the property contains a federally listed threatened or endangered species that may be affected by a permit decision. In the event that listed species are involved and a Corps permit is required for impacts to jurisdictional waters, the Corps must initiate consultation with US Fish and Wildlife Service (USFWS) or the National Marine Fisheries Service, (NMFS) pursuant to Section 7 of the ESA (16 USC 1536; 40 CFR § 402). If formal consultation is required, USFWS or NMFS will issue a biological opinion stating whether the permit action is likely to jeopardize the continued existence of the listed species, recommending reasonable and prudent measures to ensure the continued existence of the species, establishing terms and conditions under which the project may proceed, and authorizing incidental take of the species.

For discretionary permit actions by non-federal entities, Section 10 of the ESA provides a mechanism for obtaining take authorization through submittal and approval of a Habitat Conservation Plan that details species impacts, measures to minimize or mitigate such impacts, and funding mechanisms to implement mitigation requirements.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) implements international treaties devised to protect migratory birds and any of their parts, eggs, and nests from activities such as hunting, pursuing, capturing, killing, selling, and shipping, unless expressly authorized in the regulations or by permit. The regulations governing migratory bird permits are in 50 CFR part 13 General Permit Procedures and 50 CFR part 21 Migratory Bird Permits. Most bird species within California fall under the provisions of the Act. Excluded species include nonnative species such as house sparrow, starling, and ring-necked pheasant and native game species such as quail.

On December 22, 2017, the U.S. Department of Interior's Office of the Solicitor issued Memorandum M-37050, which states an interpretation that the Migratory Bird Treaty Act does not prohibit the accidental or "incidental" taking or killing of migratory birds. In response to the Trump Administration's attempted changes to the MBTA, eight states, including California, filed suit in September of 2018, arguing that the new interpretation inappropriately narrows the MBTA and should be vacated. On August 11, 2020, the Southern District of New York ruled in

favor of the long-standing interpretation of the MBTA to protect migratory birds, reinstating the historical ban on incidental take. Just days before leaving office, the Trump Administration finalized its pullback of MBTA regulations, despite the ruling of the federal court. On his first day in office, new President Joe Biden placed Trump's changes to the MBTA on hold, pending further review.

Fish and Wildlife Coordination Act

The USFWS also has responsibility for project review under the Fish and Wildlife Coordination Act. This statute requires that all federal agencies consult with USFWS, NMFS, and the state's wildlife agency (California Department of Fish and Wildlife, CDFW) for activities that affect, control, or modify streams and other water bodies. Under the authority of the Fish and Wildlife Coordination Act, USFWS, NMFS, and CDFW review applications for permits issued under Section 404 and provide comments to the Corps about potential environmental impacts.

3.2 State Regulations

Section 401 of the Federal Clean Water Act/Porter Cologne Water Quality Control Act

Pursuant to section 401 of the federal Clean Water Act, projects that require a Corps permit for the discharge of dredge or fill material must obtain water quality certification that confirms a project complies with state water quality standards before the Corps permit is valid. State water quality is regulated/administered by the State Water Resources Control Board and its nine Regional Water Quality Control Boards (RWQCB). A water quality certification from a RWQCB must be consistent with not only the Clean Water Act, but with the California Environmental Quality Act (CEQA), the California Endangered Species Act (CESA), and the SWRCB's requirement to protect beneficial uses of waters of the State.

The State also maintains independent regulatory authority over the placement of waste, including fill, into waters of the State under the Porter-Cologne Water Quality Control Act. Waters of the State are defined more broadly than "waters of the US" to mean "any surface water or groundwater, including saline waters, within the boundaries of the state" (Water Code section 13050(e)). Examples include, but are not limited to, rivers, streams, lakes, bays, marshes, mudflats, unvegetated seasonally ponded areas, drainage swales, sloughs, wet meadows, natural ponds, vernal pools, diked baylands, seasonal wetlands, and riparian woodlands. Waters of the State include all waters within the state's boundaries, whether private or public, including waters in both natural and artificial channels. They include all "waters of the United States"; all surface waters that are not "waters of the United States, e.g. non-jurisdictional wetlands; groundwater; and the territorial seas.

The State Water Resources Control Board's *State Wetland Definition and Procedures for Discharges of Dredge of Fill Material to Waters of the State* adopted April 2, 2019 (the Procedures) along with the *Implementation Guidance for the Procedures* dated April 2020 (the Implementation Guidance) defines a wetland as an area that *under normal circumstances, (1) has continuous or recurrent saturation of the upper substrate caused by groundwater, or*

shallow surface water, or both; (2) the duration of such saturation is sufficient to cause anaerobic conditions in the upper substrate; and (3) the area's vegetation is dominated by hydrophytes or the area lacks vegetation. The Procedures, along with the Implementation Guidance, state that the permitting authority (e.g. State Water Quality Control Board) shall rely on any wetland area delineation from a final aquatic resource report verified by the Corps. If the Corps does not require an aquatic resource delineation report, an applicant must submit a delineation of all waters, but these delineations will be verified by SWQCB's Regional Water Quality Control Board staff during application review. Similarly, if the Corps does not require a delineation, but similar information is prepared for CDFW, the applicant can submit that information to the Water Boards, who will determine if it is sufficient for the Water Board's purposes. In addition, as a matter of policy, the SWQCB/RWQCBs consider wetlands and waters determined to be non-jurisdictional by the Corps/USEPA under SWANCC or Rapanos guidance or the NWPR to remain jurisdictional as waters of the State subject to SWQCB/RWQCB jurisdiction.

The Procedures along with the Interim Guidance also include procedures for the submission, review, and approval of applications for activities that could result in the discharge of dredged or fill material to any Waters of the State and include elements of the Clean Water Act Section 404(b)(1) Alternatives Analysis Guidelines, thereby bringing uniformity to SWCQB's regulation of discharges of dredged or fill material to all waters of the state. Typically, the Corps requires a Clean Water Act 404(b)(1) Alternatives Analysis for wetland impacts greater than 0.50 acres. The Procedures require an alternatives analyses to be completed in accordance with a three tier system. The level of effort required for an alternatives analysis within each of the three tiers shall be commensurate with the significance of the impacts resulting from the discharge.

The California State Water Resource Control Board has also developed a general construction storm water permit to implement the requirements of the federal National Pollution Discharge Elimination System (NPDES) permit. Projects approved by a RWQCB must, therefore, include the preconstruction requirement for a Stormwater Pollution Prevention Plan and the post-construction requirement for a Stormwater Management Plan.

California Endangered Species Act

The State of California enacted the California Endangered Species Act (CESA) in 1984. The CESA is similar to the FESA but pertains to state listed endangered and threatened species. CESA requires state agencies to consult with the CDFW when preparing CEQA documents to ensure that the state lead agency actions do not jeopardize the existence of listed species. CESA directs agencies to consult with CDFW on projects or actions that could affect listed species, directs CDFW to determine whether jeopardy would occur, and allows CDFW to identify "reasonable and prudent alternatives" to the project consistent with conserving the species. Agencies can approve a project that affects a listed species if they determine that 'overriding considerations" exist; however, the agencies are prohibited from approving projects that would result in the extinction of a listed species.

The CESA generally prohibits the taking of state listed endangered or threatened plant and wildlife species, however, for projects resulting in impacts to state listed species, CDFW may authorize take through issuance of an Incidental Take Permit (ITP) pursuant to Section 2081 of the California Fish and Game Code. Section 2081 requires that such projects implement an approved habitat management plan or management agreement that avoids or compensates for possible jeopardy. CDFW requires preparation of mitigation plans in accordance with published guidelines that require, among other things, measures to fully mitigate impacts to State listed species. CDFW exercises authority over mitigation projects involving state listed species, including those resulting from CEQA mitigation requirements. No authorization of take under Section 2081 is permitted for species listed in state statutes as Fully Protected Species. Where Fully Protected Species are involved, projects must be designed to avoid all take of the species. CDFW cannot issue an ITP until the CEQA Lead Agency has provided documentation in the form of a Notice of Determination that the project has complied with CEQA.

California Department of Fish and Wildlife-Lake and Streambed Alteration Agreement
Section 1602 of the California Fish and Game Code requires any person, governmental agency, or public utility proposing any activity that will divert or obstruct the natural flow or change the bed, channel or bank of any river, stream, or lake, or proposing to use any material from a streambed, to first notify CDFW of such proposed activity. Based on the information contained in the notification form and a possible field inspection, CDFW may propose reasonable modifications in the proposed construction as would allow for the protection of fish and wildlife resources. Upon request, the parties may meet to discuss the modifications. If the parties cannot agree and execute a Lake and Streambed Alteration Agreement, then the matter may be referred to arbitration. CDFW cannot issue a Streambed Alteration Agreement until the CEQA Lead Agency has provided documentation in the form of a Notice of Determination that the project has complied with CEQA.

CDFW's regulations implementing the Fish and Game Code define the relevant rivers, streams, and lakes over which the agency has jurisdiction to constitute "all rivers, streams, lakes, and streambeds in the State of California, including all rivers, streams and streambeds which have intermittent flows of water." (Title 14 *California Code of Regulations* [CCR] § 720). The CDFW takes jurisdiction under its Lake and Streambed Alteration Agreement Program for any work undertaken in or near a river, stream, or lake that flows at least intermittently through a bed or channel. The CDFW does not have a methodology for the identification and delineation of the jurisdictional limits of streams except for the general guidance provided in *A Field Guide to Lake and Streambed Alteration Agreements, Section 1600-1607 California Fish and Game Code* (CDFG 1994). In making jurisdictional determinations, CDFW staff typically rely on field observation of physical features that provide evidence of water flow through a bed and channel such as observed flowing water, sediment deposits and drift deposits and that the stream supports fish or other aquatic life. Riparian habitat is not specifically defined by the Fish and Game Code but CDFW takes jurisdiction over areas within the flood plain of a body of water where the vegetation (grass, sedges, rushes, forbs, shrubs, and trees) is supported by the surface or subsurface flow.

California Department of Fish and Wildlife-Fish and Game Code Section 3503, 3503.5 and 3513. The State of California also incorporates the protection of nongame birds and birds of prey, including their nests, in Sections 3503, 3503.5, and 3513 of the California Fish and Game Code. Section 3503 of the Fish and Game Code makes it unlawful to take, possess, or needlessly destroy the nests or eggs of any bird. Section 3503.5 makes it unlawful to take or possess birds of prey (hawks, eagles, vultures, owls) or destroy their nests or eggs. In December of 2018, California issued new guidance specifying that state law includes "a prohibition on incidental take of migratory birds, notwithstanding any federal reinterpretation of the Migratory Bird Treaty Act" by the Department of Interior.

California Department of Fish and Wildlife Fish- Sensitive Plant Communities.
CDFW has designated special status natural communities which are considered rare in the region, rank as threatened or very threatened, support special status species, or otherwise receive some form of regulatory protection. Sensitive plant communities are those natural plant communities identified in local or regional plans, policies, ordinances, regulations, or by the CDFW which provide special functions or values. Documentation pertaining to these communities, as well as special status species (including species of special concern), is kept by CDFW as part of the California Natural Diversity Data Base (CNDDB). All known occurrences of sensitive habitats are mapped onto 7.5 minute US Geological Survey (USGS) topographic quadrangle maps maintained by the CNDDB. Sensitive plant communities are also identified by CDFW on their List of California Natural Communities Recognized by the CNDDB. Impacts to sensitive natural communities must be considered and evaluated under CEQA.

California Department of Fish and Wildlife- Species of Special Concern
CDFW tracks species in California whose numbers, reproductive success, or habitat may be threatened. Species that may be considered for review are included on a list of "Species of Special Concern" developed by the CDFW. Even though these species may not be formally listed under FESA or CESA, such plant and wildlife species must be evaluated during the CEQA review of development projects, and mitigation should be developed to prevent significant impacts to such species.

California Department of Fish and Wildlife- Fully Protected Animal Species
The classification of Fully Protected was an effort by the State of California in the 1960's to identify and provide additional protection to those animals that were rare or faced possible extinction. Most Fully Protected species have also been listed as threatened or endangered species under state endangered species laws and regulations. Species classified as Fully Protected Species by the CDFW may not be taken or possessed at any time and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research and relocation of the bird species for the protection of livestock (as per California Fish and Game Code Section 3511(a)(1)).

California Native Plant Society

The California Native Plant Society (CNPS) maintains a list of plant species native to California that have low numbers, limited distribution, or are otherwise threatened with extinction. This information is published in the Inventory of Rare and Endangered Plants of California (CNPS 2014: https://www.cnps.org/cnps/rareplants/inventory/). Potential impacts to populations of CNPS-listed plants receive consideration under CEQA review, especially for those plant species including in Lists 1 and 2. The following identifies the definitions of the CNPS listings: https://www.cnps.org/cnps/rareplants/ranking.php

California Rare Plant Rank 1A:	Plants presumed extirpated in California and either rare or extinct elsewhere.
California Rare Plant Rank 1B:	Plants rare, threatened, or endangered in California and elsewhere.
California Rare Plant Rank 2A:	Plants presumed extirpated in California, but more common elsewhere.
California Rare Plant Rank 2B:	Plants rare, threatened, or endangered in California, but more numerous elsewhere.
California Rare Plant Rank 3:	Plants about which more information is needed – a review list.
California Rare Plant Rank 4:	Plants of limited distribution – a watch list.

3.3 City of American Canyon Policies

City of American Canyon General Plan

In addition to federal and state regulations, the development of the property must be accomplished consistent with the land use designations and natural resource and other policies of the City of American Canyon General Plan. The objectives and policies of the City General Plan related to Biological Resources are under the Goal 8 of the Plan, which is "Protect and preserve the significant habitats, plants and wildlife that exist in the City and its Planning Area." Relevant objectives intended to obtain the overall goal and policies of the City related to biological resources are listed below:

Objective 8.1: Maintain data and information regarding areas of significant biological value within the Planning Area to facilitate resource conservation and the appropriate management of development.

> Policy 8.1.1: Acquire and maintain the most current information available regarding the status and location of sensitive biological elements (species and natural communities) within the City and, as appropriate, within the Sphere of Influence and Urban Limit Line.
>
> Policy 8.1.4: Regularly monitor and review developments proposed within the City's Planning Area to assess their impacts on local biological resources and to recommend

appropriate mitigation measures that the developer and/or government agency can implement.

Objective 8.2: Balance the preservation of natural habitat areas, including coastal saltmarsh, mixed hardwood forest, oak savannah, and wetland and riparian habitats, with new development in the City.

Policy 8.2.1: Land use applications for developments located within sensitive habitats, including coastal saltmarsh, mixed hardwood forest, oak savannah, and riparian habitats or with areas potentially occupied by vernal pools shall be accompanied by sufficient technical background data to enable an adequate assessment of the potential for impacts on these resources, and possible measures to reduce any identifiable impacts. In addition to examining the General Plan for information on these sensitive habitats, an on-site assessment shall be conducted by a City approved qualified biologist to determine if sensitive habitats exist on-site. In instances where the potential for significant impacts exists, the applicant must submit a Biological Assessment Report prepared by a qualified professional.

Objective 8.3: Protect natural drainages and riparian corridors within the City of American Canyon Planning Area.

Policy 8.3.1: Review proposed developments in wetlands and riparian habitats to evaluate their conformance with the following policies and standards:

a. The development plan shall fully consider the nature of existing biological resources and all reasonable measures shall be taken to avoid significant impacts, including retention of sufficient natural open space and undeveloped buffer zones.

b. Development shall be designed and sited to preserve watercourses, riparian habitat, vernal pools, and wetlands in their natural condition, unless these actions result in an unfeasible project, in which case habitat shall be replaced in accord with subsection "g" (below).

c. Where riparian corridors are retained, they shall be protected by an adequate buffer width of a minimum 100-foot protection zone from the edge of the tree, shrub, or herb canopy.

d. Development shall incorporate habitat linkages (wildlife corridors) to adjacent open spaces, where appropriate and feasible.

e. Development shall incorporate fences, walls, vegetative cover, or other measures to adequately buffer habitat areas, linkages, or corridors from built environment.

f. Roads and utilities shall be located and designed such that conflicts with biological resources, habitat areas, linkages or corridors are avoided where feasible.

g. Future development shall utilize appropriate open space or conservation easements in order to protect sensitive species or their habitats.

h. Future development shall mitigate unavoidable adverse impacts to waters of the United States and waters of the State, wetlands, and riparian habitats (pursuant to the Federal Clean Water Act, Porter-Cologne Water Quality Control Act and the California Fish and Game Code, Section 1600 et seq.) by replacement on an in-kind basis. Furthermore, replacement shall be based on a ratio determined by the California Department of Fish and Game, and/or US Army Corps of Engineers in order to account for the potentially diminished habitat values of replacement habitat. Such replacement should occur on the original development site, whenever possible. Alternatively, replacement can be affected, subject to state and federal regulatory approval, by creation or restoration of replacement habitats elsewhere (offsite but preferably within the City's Planning Area), protected in perpetuity by provision for an appropriate conservation easement or dedication.

Policy 8.3.6: Preserve and integrate the City's natural drainages in new development, as opposed to their channelization or undergrounding, emphasizing opportunities for the development of pedestrian paths and greenbelts along their lengths throughout the City.

Objective 8.4: Protect local vernal pools as well as the habitats of endangered species living within the City of American Canyon's Planning Area.

Policy 8.4.1: Require that development plans incorporate all reasonable mitigation measures to avoid significantly impacting vernal pools for projects located within the City of American Canyon's Planning Area.

Policy 8.4.3: Encourage activities that improve the biological value and integrity of the City's natural resources through vegetation restoration, control of alien plants and animals, and landscape buffering.

4.0 EXISTING BIOLOGICAL SETTING

The 207.8-acre Project Site is located in the northwestern portion of the City of American Canyon, Napa County, California. A regional location map for the Project Site is shown in Figure 1 and the area in the vicinity of the site is shown in Figure 2. Figure 3 shows the location of the Project Site on the Cuttings Wharf, California, United States Geological Survey 7.5-minute topographic quadrangle, Township 4 North, Range 4 West, Sections 13 and 14 (Latitude 38° 11' 50" North; Longitude 122° 15' 36" West).

Figure 4 is an aerial photograph of the Project Site that portrays existing site conditions and the surrounding land uses. The Project Site is bound by industrial development in the Green Island Business Park to the west, the Napa Logistics Project and Devlin Road to the north, and the Napa Branch Line of the Southern Pacific Railroad to the east. A wine distribution warehouse is to the southeast and a stone supply business to the southwest.

The description of the biological setting for the property is based on field visits to the site by HBG Senior Environmental Scientist Gary Deghi, Senior Wetland Scientist Robert Perrera, and Wildlife Biologist Emilie Strauss between December of 2020 and April of 2021. In addition, HBG independently reviewed and incorporated a number of studies previously prepared for the Project Site by other consultants and conducted additional specialized studies using species experts as part of work in preparing this document.

Previously prepared biological studies pertaining to the site included an aquatic resources delineation prepared by Monk & Associates (2016) and surveys for federally listed vernal pool brachiopods conducted by both LSA Associates (2016) and Monk & Associates (2017). HBG included a Habitat Assessment for the federally listed threatened California red-legged frog prepared by Dr. Mark Jennings and rare plant surveys, currently underway, by Dr. Brent Helm during the 2021 flowering season. Also relevant to the biological evaluation were Biological Resource Reports prepared by Monk & Associates for two separate Initial Study/Mitigated Negative Declarations prepared by the City of American Canyon for projects with project boundaries either shared with or adjacent to the Project Site. These include Biological Resource Reports for the Devlin Road Extension Project (Monk & Associates 2018) and the Green Island Road Reconstruction and Widening Project (Monk & Associates 2019).

4.1 Climate

The Project Site is located in the City of American Canyon, which is part of the greater north San Francisco Bay area. Like other portions of northern California, American Canyon experiences a Mediterranean climate characterized by warm, dry summers and cool, wet winters. The project area typically exhibits annual low/high temperatures between 40 and 80 degrees Fahrenheit and an annual average rainfall of approximately 20 inches.

4.2 Hydrology

The 207.8-acre Project Site is currently undeveloped land with a range of elevations between 35 and 50 feet msl. The headwaters of No Name Creek occurs within the northwestern portion

of the Project Site. The Project Site gently slopes from east to west at about zero to two percent to the northwestern corner of the property where No Name Creek flows off the site through the Napa Logistics wetland preserve and is hydrologically connected to Fagan Slough which flows into the Napa River. The majority of wetlands that occur throughout the site and are supported by direct precipitation.

As shown on Figure 7 the Study Area primarily lies within the USGS Hydrologic Unit Code (HUC) 10-digit subwatershed of the Tulucay Creek-Frontal San Pablo Bay Estuaries (1805000204).

4.3 Topography and Soils

The majority of the Project Site is relatively flat at approximately 40 feet mean sea level and a total elevation variance of 30 feet. The Project Site generally slopes at about zero to two percent with two highpoints to the southeast and southwest of the gradually sloping north toward No Name Creek. Although the remaining portions of the Project Site are relatively flat, grazing and inundation in topographic low areas has created a hummocky landscape with depressional microrelief. As a result, there are small seasonal wetlands and swales scattered throughout the site. Other large, and deep wetlands occur on the eastern and southern portions of the site. In the southeastern portion of the Project Site a berm confines surface water sheet flows creating several inundated depressional features.

Soil survey information for the Project Site was obtained from the National Resources Conservation Service Web Soil Survey (NRCS 2021). Three different soil types were mapped by NRCS within the Project Site. The mapped soil units include: Clear Lake clay drained (116), 0 to 2 percent slopes, Haire loam (146), 2 to 9 percent slopes, and Haire clay loam (148), 2 to 9 percent slopes (USDA 1972). A soil map for the Project Site is shown in Figure 8.

The Clear Lake series consists of poorly drained soils on old alluvial fans and basins. Elevation is 25 to 2000 feet. These soils formed in alluvium derived from sedimentary rock. The plant cover is annual grasses and forbs. The mean annual precipitation is 25 to 35 inches and the mean annual temperature is 59 to 63 degrees. Clear Lake clay drained soil is classified as a hydric soil (i.e., those soils that form in wetlands) by the NRCS.

The Haire Loam series consists of moderately well-drained soils, slow to rapid runoff, and very slow permeability on alluvial fans and terraces. Elevation is 20 to 2,402 feet. These soils formed in alluvium derived from sedimentary rock. The plant cover is annual grasses and forbs. The mean annual precipitation is 25 to 30 inches and the mean annual temperature is 57 to 61 degrees Fahrenheit. Haire Loam soil is not classified as hydric soil (i.e., those that form in wetlands) by the NRCS.

The Haire clay loam series consists of moderately well-drained soils, with high run off, on alluvium derived from sedimentary rock. Elevation is 20 to 2402 feet. The plant cover is annual grasses and forbs. The mean annual precipitation is 25 to 30 inches and the mean annual

temperature is 57 to 61 degrees Fahrenheit. Haire Clay Loam is not classified as a hydric soil (i.e., those that form in wetlands) by the NRCS.

4.4 Plant Communities

Vegetation communities are assemblages of plant species growing in an area of similar biological and environmental factors. Vegetation communities and habitats at the Project Site were identified based on the currently accepted List of Vegetation Alliances and Associations or Natural Communities (CDFW 2010). The list is based on A Manual of California Vegetation, Second Edition (Sawyer et al 2009), which is the National Vegetation Classification applied to California. The Project Site contains two habitat types: Non-native Grassland and Coastal and Valley Freshwater Marsh in the form of seasonal wetlands and swales. This identification of habitat types on the property matches the findings of Monk & Associates as stated in their wetland delineation technical letter report submitted to the USACE (Monk & Associates 2016). An inventory of plant species found on the Giovannoni property during biological studies conducted by Monk & Associates is provided in Attachment 2, Table 1.

Non-native annual grasslands. Non-native annual grasslands, dominated by introduced annual grasses and forbs, comprise the predominant habitat types on the property. The dominant species in the grasslands were identified when Monk & Associates conducted their aquatic resources delineation on the Project Site and report in their technical report submitted to the Corps of Engineers (Monk & Associates 2016). Dominant non-native annual grass species on the project site include Italian ryegrass (*Festuca perennis*), Mediterranean barely (*Hordeum marinum* ssp. *gussoneanum*), medusa head (*Elymus caput-medusae*), and soft chess (*Bromus hordeaceus*). Common non-native forbs found on the Project Site include bird's foot trefoil (*Lotus corniculatus*), subterranean clover (*Trifolium subterranean*), broad-leaf filaree (*Erodium botrys*), English plantain (*Plantago lanceolata*), yellow glandweed (*Parentucellia viscosa*), Mediterranean linseed (*Bellardia trixago*), spring vetch (*Vicia sativa*), and bristly ox-tongue (*Helminthotheca echioides*). Native forbs and wildflowers were also present and include yellow owl's clover (*Triphysaria versicolor* ssp. *faucibarbata*), hayfield tarplant (*Hemizonia congesta* ssp. *luzulifolia*), and coastal tarweed (*Deinandra corymbosa*). Other common species noted by HBG biologists during winter surveys in 2020 included species such as Harding grass (*Phalaris aquatica),* rip-gut brome (*Bromus diandrus*), field bindweed (*Convolvulus arvensis*), and sweet fennel (*Foeniculum vulgare*). Other species included scattered coyote brush (*Baccharis pilularis*) and Himalaya berry (*Rubus armeniacus*), especially around the edges of the property.

Seasonal Wetlands and Swales. Seasonal wetlands on the property are vegetated with a variety of native and non-native species adapted for life in saturated soil conditions. Monk & Associates noted the vegetation in the seasonal wetlands and swales as being dominated by primarily native species such as annual semaphore grass (*Pleuropogon californicus* var. *californicus*), creeping spikerush (*Eleocharis macrostachya*), iris-leaved rush (*Juncus xiphioides*), California coyote thistle (*Eryngium aristulatum* var. *aristulatum*), meadow barley (*Hordeum brachyantherum*), smooth goldfields (*Lasthenia glaberrima*), Great Valley popcorn flower (*Plagiobothrys stipitatus* var. *micranthus*), and wavy stemmed popcorn flower (*P. undulatus*),

along with a few non-native wetland species such as rabbit's foot grass (*Polypogon monspeliensis*) and brass buttons (*Cotula coronopifolia*). Other plants noted in the seasonal wetlands during winter surveys conducted by HBG included species such as annual hairgrass (*Descampsia danthanoides*), Mediterranean barley (*Hordeum marinum* ssp. *gussoneanum*), saltgrass (*Distichlis spicata*), pennyroyal (*Mentha pulegium*), rough cocklebur (*Xanthium strumarium*), tall flat-sedge (*Cyperus eragrostis*), and swamp timothy (*Crypsis schoenoides*), and in some areas of deeper inundation, broadleaf cattail (*Typha latifolia*).

4.5 Animal Populations

The Project Site provides limited habitat for wildlife species, mostly those adapted to open areas and farm fields and disturbed environments. Grasses and herbaceous plants within the Project Site provide limited nesting and roosting sites for birds, and cover and foraging habitat for species of birds, mammals, reptiles, and amphibians. Seasonal wetlands provide wildlife with a seasonal water source that supports various animal species during the winter and spring months and sometimes into the early summer. Amphibians will lay their eggs in seasonal wetland habitats and complete much of their life cycle in the wetlands. No Name Creek would be considered a wildlife corridor, but the property is nearly entirely surrounded by development so the extent of wildlife corridors on the property is limited.

A number of wildlife species were documented during a winter season survey conducted at the Project Site by wildlife biologist Gary Deghi of HBG on December 10, 2020. All species documented at the site are common to abundant in the region and would be expected in the non-native grasslands and seasonal wetlands present at the site. Bird species documented included various species adapted to grasslands and open areas including Canada goose (*Branta canadensis*), California gull (*Larus californicus*), mourning dove (*Zenaida macroura),* Eurasian collared-dove (*Streptopelia decaocto*), rock pigeon (*Columba livia*), American crow (*Corvus brachyrhynchos*), common raven (*Corvus corax*), black phoebe (Sayo*rnis nigricans*), Say's phoebe (*Sayornis saya*), savannah sparrow (*Passerculus sandwichensis*), red-winged blackbird (*Agelaius phoeniceus),* and western meadowlark (*Sturnella neglecta*). Other species in taller vegetation and landscaping around the edges of the site and just off-site included California scrub-jay (*Aphelocoma californica*), bushtit (*Psaltriparus minimus*), northern mockingbird (*Mimus polyglottos)*, European starling (*Sturnis vulgaris*), white-crowned sparrow (*Zonotrichia leucophrys*), California towhee (*Melozone crissalis*), house finch (*Haemorhous mexicanus*), and lesser goldfinch (*Spinus psaltria*). Raptors (birds of prey) observed foraging over the grasslands and wetlands of the Project Site were fairly common during the winter survey and included American kestrel (*Falco sparverius*), white-tailed kite (*Elanus leucurus*), red-tailed hawk (*Buteo jamaicensis*), Northern harrier (*Circus hudsonius*), and turkey vulture (*Cathartes aura*).

HBG wildlife biologist Emilie Strauss conducted a spring season site reconnaissance on April 16, 2021 on the Project Site. Many of the bird species observed included species observed during the winter, but additional resident species observed during the April visit included ring-necked pheasant (*Phasianus colchicus*), great blue heron (*Ardea herodia*), great egret (*Ardea alba*), and killdeer (*Charadrius vociferus*). Additional species added during the spring survey included

spring arrivals of migrant species. Breeding season raptor observations included foraging Northern harrier (a state designated species of special concern for nesting habitat that was also observed foraging over the site in winter), as well as foraging by state listed threatened Swainson's hawk (*Buteo swainsoni*). A California Fully Protected golden eagle (*Aquila chrysaetos*) was also observed over the Project Site being harassed by the Swainson's hawk and flying low exhibiting foraging behavior. These three special status raptor species have nested in this part of Napa County in the past, and it is entirely possible these individuals could be nesting somewhere in the vicinity of the Project Site. HBG wildlife biologist Emilie Strauss drove about 10 miles of local roads surrounding the Project Site to inspect trees for raptor nest structures. No Swainson's hawk nest structures were observed. Additional species observed in the spring survey included cliff swallow (*Petrochelidon pyrrhonota*) and barn swallow (*Hirundo rustica*).

During their biological studies related to the Green Island Road Widening and Devlin Road Extension Projects in 2018 and 2019, Monk & Associates observed several species of waterfowl and shorebirds in the on-site seasonal wetlands. These species were not observed during the December 10, 2020 or April 16, 2021 surveys by HBG as surface ponding was lacking on the site then due to the paucity of rain. These species included mallard (*Anas platyrhynchos*), American wigeon (*Anas americana),* greater yellowlegs (*Tringa melanoleuca*), long-billed curlew (*Numenius americanus*), marbled godwit (*Limosa fedoa*), western sandpiper (*Calidris mauri*), and Wilson's snipe (*Gallinago delicata*).

No amphibians were documented on the property by HBG, but Pacific treefrog (*Pseudacris regilla*) was noted by Monk & Associates biologists while studying the Green Island Road Extension. Reptile sightings at the site by HBG included western fence lizard (*Sceloperus occidentalis);* other reptiles likely include Pacific gopher snake (*Pituophis catenifer)* and common garter snake (*Thamnophis sirtalis elegans)*. Observed evidence of mammals on the site by HBG were black-tailed jackrabbit (*Lepus californicus*), dens of Botta's pocket gopher (*Thomomys bottae*) and California vole (*Microtus californicus*), several California ground squirrels (*Otospermophilus beecheyi*) in a rubble pile in the southwestern portion of the site, and three mule deer (*Odocoileus hemionus*) in the southeastern portion of the property. Monk & Associates apparently observed raccoon (*Procyon lotor*) while conducting studies for the Devlin Road Extension Project. Other expected mammals would be those adapted to disturbed, urban environments such as Virginia opossum (*Didelphis virginiana*), deer mouse (*Peromyscus maniculatus*), and striped skunk, (*Mephitis mephitis*).

4.6 Wetlands

Aquatic Resources Delineation Methodology. Monk & Associates conducted an aquatic resources delineation on the Project Site in 2016. Field work for the delineation was conducted during the period of April 15 to May 26, 2016. Monk & Associates biologists used the Corps' 1987 Wetlands Delineation Manual in conjunction with the regional supplement for the Arid West Region to prepare this wetland delineation. A jurisdictional determination request and the Draft Aquatic Resources Delineation Map were prepared in compliance with the Corps' 2016 Minimum Standards for Acceptance of Aquatic Resources Delineation Reports and the

2016 Updated Map and Drawing Standards for the South Pacific Division Regulatory Program (Monk & Associates 2016).

Vegetation, hydrology, and soils information were taken at 142 data points. Data points were mapped using a Trimble Pro-XR Global Positioning System (GPS) having sub-meter accuracy. The delineation map was made from the GPS files using ArcMap 10.2. All spatial data were projected into the California State Plane, NAD 83 coordinate system, Zone 2. Using GPS technology, the boundaries (within 30 inches) of each delineated wetland was transferred to an aerial photograph of the Project Site (Monk & Associates 2016).

Aquatic Resources Delineation Results. The Aquatic Resources Delineation map prepared by Monk & Associates was submitted to the San Francisco District of the USACE on August 29, 2016 and was confirmed by letter from the USACE dated November 8, 2016. The wetlands found on the Project Site as mapped by Monk & Associates (2016) and verified by the USACE are provided in Attachment 4. The mapped areas classified as wetlands exhibited a dominance of hydrophytic vegetation, as well as hydric soils and wetland hydrology. Hydrological indicators in mapped wetlands included the presence of oxidized rhizospheres along living roots (C3), surface soil cracks (B6), algal matting (Biotic Crust B12), aquatic invertebrates (B13), and vegetation suppression (indicating long-term inundation) within these wetland areas. Evidence of hydric soils included Redox Dark Surface F6 and Depleted Matrix F3 as defined in the approved regional supplement for the Arid West Region and the Field Indicators of Hydric Soils in the United States (Monk & Associates 2016).

The majority of the seasonal wetlands on the Project Site gradually drain north toward No Name Creek. No Name Creek, within the Project Site, does not exhibit an ordinary high water mark, and is therefore categorized as a seasonal wetland. No Name Creek flows off the Project Site to the west before draining into Fagan Slough, a tidal water of the United States. Fagan Slough is tributary to the Napa River, a traditional navigable water (TNW) that flows to San Pablo Bay. Therefore, the 11.93 acres of seasonal wetlands in the north and southwest corner of the site are regulated as “waters of the U.S.” pursuant to Section 404 of the Clean Water Act and are subject to USACE jurisdiction (see Attachment 4). Several features in the southeastern portion of the Project Site are mapped as “isolated” seasonal wetlands since they do not have hydrologic connectivity to any water of the U.S. The “isolated” features are contained within discreet topographic depressions, surrounded by uplands and berms that are higher in elevation, thereby isolating these features from any water of the U.S. A total of 0.84 acre of “isolated” features that are mapped on the Project Site are not subject to USACE jurisdiction as shown on Exhibit 6.

The total area of USACE jurisdictional wetlands mapped on the Project Site is 11.93 acres. The total area of “isolated” wetlands mapped on the Project Site is 0.84 acre. HBG has determined that the areas mapped as isolated wetlands and not subject to jurisdiction of the USACE under the federal Clean Water Act would be subject to the wetland criteria of the state Porter-Cologne Water Quality Control Act and the jurisdiction of the San Francisco Bay Regional Water

Quality Control Board as a Water of the State. A total of 12.77 acres of wetlands would be subject to the regulatory jurisdiction of the San Francisco Bay RWQCB (SFBRWQCB) as Waters of the State. The portion of the Project Site along the northern boundary of the site contained within the confines of No Name Creek would be subject to the regulatory jurisdiction of the California Department of Fish and Wildlife (CDFW) under Fish and Game Code Section 1602.

4.7 Special Status Species

Special status species include those species listed by the federal and state governments as endangered, threatened, or rare or candidate species for these lists. Endangered or threatened species are protected by the federal Endangered Species Act of 1973 as amended, the California Native Plant Protection Act of 1977, and the California Endangered Species Act of 1970. The California Environmental Quality Act (CEQA) provides additional protection for unlisted species that meet the "rare" or "endangered" criteria defined in Title 14, California Code of Regulations Section 15380. Special status species also include those species listed by CDFW as Species of Concern which face extirpation in California if current population and habitat trends continue, those listed as Fully Protected by CDFW (a designation that provides additional protection to those animals that are rare or face possible extinction), and bird species designated as Bird Species of Conservation Concern by the USFWS. These state and federal Species of Concern must be evaluated in the context of evaluation under CEQA, which also requires evaluation of impacts to plant species on California Native Plant Society (CNPS) Lists 1 and 2. Special status species included in CEQA review also include bat species that have been designated with conservation priority by the Western Bat Working Group.

The CDFW maintains records for the distribution and known occurrences of special status species and sensitive habitats in the California Natural Diversity Database (CNDDB). The CNDDB is organized into map areas based on 7.5 minute topographic quadrangle maps produced by the USGS. All known occurrences of special status species are mapped onto quadrangle maps maintained by the CNDDB. The database gives further detailed information on each occurrence, including specific location of the individual, population, or habitat (if possible) and the presumed current state of the population or habitat. The Project Site is within the encompasses Cuttings Wharf 7.5 minute quadrangle map.

Tables 2 and 3 in Attachment 2 present a list of special status plants and animals, respectively, that have been reported by the CNDDB in the project vicinity within 10 miles of the site. An evaluation of the potential for all potential sensitive species to occur at the site is included in Tables 2 and 3 in Attachment 2. Key species are discussed below.

4.7.1 Special Status Plant Species

A list of special status plants with potential to occur on the Project Site was developed from the CNDDB. A complete list of special status plant species occurring in the vicinity of the property is included in Table 2 in Attachment 2. The table includes all species of flora mentioned in the CNDDB within approximately ten miles of the site.

A number of special status plant species listed in Table 2 in Attachment 2 are known to occur in the Napa area. No special-status plants have been mapped on or adjacent the Project Site. However, according to the CNPS' Inventory and the California Department of Fish and Wildlife's (CDFW) CNDDB, a number of special-status plant species are known to occur in the Project Site vicinity. No special-status plants were identified on the Project Site by Monk & Associates while conducting various studies on the property in 2016, including an aquatic resources delineation and other evaluations conducted during the March to July flowering season of 2016. However, these studies did not constitute protocol surveys. Therefore, HBG has retained Dr. Brent Helm to conduct protocol rare plant surveys during the 2021 flowering season. These surveys are currently underway, and a special status plant survey report is expected to be completed by July of 2021.

4.7.2 Special Status Animal Species

Animal species noted in the CNDDB as occurring within a 10-mile radius of the site, or that are known to occur in the general vicinity based on the knowledge of HBG biologists, are discussed in Table 3 in Attachment 2. A number of special status animal species are noted in the CNDDB as occurring in the general vicinity of the Project Site with habitat requirements similar to the habitats present on the Project Site. These species include vernal pool fairy shrimp (*Branchinecta lynchi*), California red-legged frog (CRLF, *Rana draytonii),* Western pond turtle (*Emmys marmorata*), Swainson's hawk (*Buteo swainsoni*), golden eagle (*Aquila chrysaetos*), northern harrier (*Circus hudsonius*), burrowing owl (*Athene cunicularia*) and tricolored blackbird (*Aegelaius tricolor*). These species are discussed in detail below. CDFW is also concerned over rapid declines in populations of monarch butterflies (*Danuas plexippus*), and a discussion of this species in relation to the proposed project is also included below.

None of the other animal species discussed in the table have the potential to occur on the site. This finding is made based on the habitat requirements of species listed in the table and is based on field review of habitats present at the site and the immediate vicinity and an evaluation of the suitability of on-site habitats to support these species.

Monarch Butterfly

Background. The monarch (*Danuas plexippus*) is designated as a California Terrestrial and Vernal Pool Invertebrate of Conservation Priority and has recently been advanced as a candidate species for listing under the federal Endangered Species Act. The species is well-known for its north-south migrations from Canada to Mexico which span the lives of several generations. Monarch butterfly winter roost sites, typically used between October and February, extend along the West Coast from Mendocino County in northern California, south to Baja California in Mexico. Winter roosts consist of hundreds or thousands of monarchs in wind-protected tree groves close to sources of nectar and water. On the California coast, these roosts usually form in eucalyptus, but Monterey pine and Monterey cypress groves are also used. Monarch populations across North America have fallen by as much as 90 percent in the last two decades and in February 2015, the USFWS showed that nearly a billion monarchs had vanished from overwintering sites since 1990. The larval host plant for monarchs is milkweeds,

primarily milkweeds of the genus *Asclepias*. The main reason for the decline has been attributed to herbicides used by farmers and homeowners on milkweed, the butterfly's larval host plant.

Occurrence in the Project Area. No trees are present on the Project Site so there is no possibility for the presence of a monarch overwintering site on the Project Site. Several biological investigators have studied the Project Site and none have reported the presence of milkweed plants, primarily of the genus *Asclepias*, that serve as the larval host plant for monarchs. Monk & Associates prepared an inventory of plants present on the Giovannoni site as part of a wetland delineation conducted at the site in 2016 (this list is included herein as Table 1 in Attachment 2), and no milkweed plants of the genus *Asclepias* are noted in the table. No suitable habitat for monarch butterflies is found on the site. As part of Dr. Brent Helm's protocol rare plant surveys he is currently conducting, any observations of milkweed plants of the genus *Asclepias* will be recorded. The presence of an individual monarch butterfly at the site would be purely incidental and not related to the presence of larval host plants for breeding or of suitable overwintering sites.

Vernal Pool Fairy Shrimp

Background. Vernal pool fairy shrimp was designated as threatened in its entire range on September 19, 1994 (Federal Register 59:48136-48153). Critical habitat for this species was originally designated on August 6, 2003 (Federal Register 68: 46683-46867), and the designation was revised on August 11, 2005. Critical habitat unit designations by individual fairy shrimp species were published on February 10, 2006 (Federal Register 71:7117). The project site is approximately 0.40-mile southeast of designated critical habitat.

The vernal pool fairy shrimp (*Branchinecta lynchi*) is a small aquatic crustacean that ranges in size from ½ to one inch long that is federally listed as a threatened species. Fairy shrimp feed on algae, bacteria, protozoa, rotifers, and bits of detritus. The vernal pool fairy shrimp occupies a variety of different vernal pool habitats, from small, clear, sandstone rock pools to large, turbid, alkaline, grassland valley floor pools. It tends to occur in smaller pools (less than 0.05-acre) that are most commonly found in grass or mud bottomed swales, or basalt flow depression pools in unplowed grasslands. It has also been collected in large vernal pools (e.g. 25 acres). Vernal pool fairy shrimp have been collected from early December to early May (USFWS 2005).

Vernal pool fairy shrimp populations are presently known from localities in California, extending from Stillwater Plain in Shasta County through most of the length of the Central Valley to Pixley in Tulare County, and along the central coast range from northern Solano County to Pinnacles National Park in San Benito County. Disjunct populations are located near Soda Lake in San Luis Obispo County, in the mountain grasslands of northern Santa Barbara County, on the Santa Rosa Plateau in Riverside County, and near Rancho California in Riverside County. Vernal pool fairy shrimp mature quickly and can persist in short-lived shallow pools and longer lasting pools that remain later in the spring. This species inhabits pools with clear to tea-colored water, most commonly in grass or mud bottomed swales, or basalt flow depression pools in unplowed

grasslands, but sometimes in sandstone rock outcrops and alkaline vernal pools. The water in these pools has low total dissolved solids, conductivity, alkalinity, and chloride.

Occurrence in the Project Area. Formal protocol surveys for vernal pool brachiopods, including the federally listed threatened vernal pool fairy shrimp (*Branchinecta lynchi*), were conducted on the Project Site with negative findings. Surveys were conducted following USFWS survey protocol (USFWS 2015) as approved by the USFWS on August 18, 2016. Wet season surveys were completed by Monk & Associates (Monk and Associates 2017) between November 2016, when it could be documented that wetland features on the property had at least 1 inch of standing water, and the end of February 2017. Dry season surveys were conducted by LSA Associates (LSA 2016) during the summer of 2016. No vernal pool brachiopods or their cysts were found during the wet season and dry season protocol surveys conducted at the Project Site. Although vernal pool seasonal wetlands occur on the Project Site, based on the results of the protocol surveys conducted, it can be definitively stated that the federally listed threatened vernal pool fairy shrimp does not occur on the Project Site.

California Red-legged Frog

Background. The California red-legged frog (CRLF, *Rana draytonii)* is a federally threatened species and California Species of Special Concern. The historical range of the California red-legged frog extended from the vicinity of mid-Mendocino County, southward to northwestern Baja California, Mexico and inland to approximately Redding in Shasta County (61 Federal Register 25813; 75 Federal Register 12816). The frog has sustained a 70 percent reduction in its geographic range. The project area is not part of the critical habitat designated under the Endangered Species Act for the CRLF.

California red-legged frogs have been observed in aquatic and terrestrial habitats, including marshes, streams, lakes, reservoirs, ponds and other permanent, or near permanent, sources of water. Although they occur in ephemeral streams or ponds, CRLF are expected to thrive in permanent deep-water pools with dense stands of overhanging willows and emergent vegetation, and suitable sites for basking. However, they have been observed in a variety of aquatic environments, including stock ponds and artificial pools with little to no vegetation. California red-legged frogs usually are observed near water but can move long distances over land between water sources during the rainy season.

The life cycle and patterns of movement of the CRLF have evolved along with the local California climate of wet, cool winters and dry, warm summers. With the onset of the winter rains, CRLF move from dry-season refuges to ponds and streams that can support breeding and successful tadpole development. Tadpoles generally take until late summer or early fall to complete metamorphosis, and then the maturing young frogs (metamorphs) move to aquatic areas to take cover from predators. Adult frogs often remain year-round at perennial ponds with deep water, but some depart for dry season refuges once breeding is over. Juveniles (frogs that are older than metamorphs but not yet sexually mature) disperse widely over the landscape during the first winter and will take residence in almost any water source. During the

dry months of summer and fall, CRLF seek suitable dry season refuge sites that may include deep water holes in drying streams, springs and spring boxes, seeps, and small mammal burrows (especially in or near vegetation). However, CRLF need to hydrate at least every couple of days in order to survive. Thus, such small mammal refuge sites must be close to a permanent water source for frogs to rehydrate. To find these refuges, frogs will travel several hundred yards where suitable refuges are abundant and up to three miles in moist coastal areas. Often, long distance movements are in a relatively straight line over hills and drainages between the beginning and end points.

Occurrence in the Project Area. Monk & Associates (2018, 2019) conducted surveys for special status plants and animals, including CRLF, on the small portion of the site slated for road improvements for the Devlin Road and Green Island Road improvements. No CRLF were encountered during these surveys, and they found that the wetlands associated with the road improvements were inundated to only 3 to 4 months of the year (too short to support CRLF breeding) and were too shallow and seasonal to support breeding by CRLF.

Herpetologist Dr. Mark Jennings of Rana Resources conducted a protocol Phase 1 Habitat Assessment for CRLF in 2021 as part of the studies conducted for this Biological Resources Report. Dr. Jennings reported that the project site lacks habitat necessary to support CRLF. The closest known CRLF records to the Project Site are 0.6-2.4 miles to the east and southeast. Additional CRLF records 3.7 miles away lie within Critical Habitat designated for this species (SOL-2 and SOL-3). All of these records lie east of Highway 29 which is a major barrier to any potential movements of CRLF to the west due to continuous traffic, highway berms, and the re-routing of drainages into culverts under the freeway. Additionally, the Project Site is completely isolated from all areas to the east by Highway 29, railroads, buildings, and other urban infrastructure, and there are no hydrologic connections with any stream channels off-site to the east of Highway 29. Finally, there is no suitable breeding or rearing habitat for CRLF on the Project Site due to the shallow and ephemeral nature of the seasonal wetlands and the lack of any suitable riparian vegetation for cover. Dr. Jennings concluded that CRLF do not occupy the Project Site. The CRLF Habitat Assessment prepared by Dr. Jennings is included as Attachment 3.

Western Pond Turtle

Background. The Western pond turtle (*Emmys marmorata*) is a state species of special concern. Pond turtles occupy ponds, marshes, rivers, streams, and irrigation ditches with aquatic vegetation. The turtles prefer aquatic habitats with calm waters, vegetated banks and emergent logs or rocks to use as basking sites. The turtles also rely on suitable upland areas of scrub and woodlands for aestival refugia and may use upland habitats up to 0.5 km from water for activities such as egg-laying. Pond turtles living in streams may vacate flood-prone areas during the rainy season. Western pond turtles occur broadly in suitable habitats throughout the state of California.

Occurrence in the Project Area. Western pond turtle is known from the project area. The nearest sighting to the Giovannoni site reported in the CNDDB is of two turtles reported in 2002 from North Slough, a location that is approximately 0.25 miles from the southern property boundary. However, suitable habitat for western pond turtle does not occur on the Giovannoni site due to the shallow and ephemeral nature of the seasonal wetlands, which are inundated for only about 3 to 4 months out of the year and even less in drought years. Suitable shrub/woodland in surrounding uplands and appropriate basking sites are also lacking. It can be definitively stated that western pond turtle does not occupy the project site due to the lack of suitable habitat.

Swainson's Hawk

Background. The Swainson's hawk (*Buteo swainsoni*) is a medium-sized hawk that is state listed in California under CESA as threatened species. This hawk is also designated by the USFWS as a Bird Species of Conservation Concern. Most Swainson's hawk territories in the Central Valley are in riparian systems adjacent to suitable foraging habitats. Valley oak, Fremont cottonwood, walnut, and large willows with an average height of about 58 feet, and ranging from 41 to 82 feet, are the most commonly used nest trees in the Central Valley (CDFW 2007), but eucalyptus is also commonly used. Swainson's hawks often nest peripherally to riparian systems of the valley as well as utilizing lone trees or groves of trees in agricultural fields. Suitable foraging areas include grasslands, pastures, alfalfa and other hay crops, and certain grain and row croplands. In the Central Valley, Swainson's hawks find suitable foraging habitat in such agricultural areas near suitable nest sites, however, nesting habitat is in decline due primarily to flood control projects, agricultural practices, and urban development. The current population of Swainson's hawk in California's Central Valley is estimated at 1,948 breeding pairs (CDFW 2007), with most of this population occurring in the area from Stanislaus County north to Butte County.

Occurrence in the Project Area. There are no trees located on the 207.8-acre Project Site, and no large trees capable of supporting nesting by Swainson's hawk in the immediate project vicinity, therefore it can be stated that Swainson's hawk does not nest in the immediate vicinity of the Project Site. The non-native grasslands and seasonal wetlands and swales found on the property provide suitable foraging habitat for Swainson's hawk that may nest away from the Project Site in areas nearby, and, indeed, a Swainson's hawk was observed foraging over the Project Site by HBG during a site reconnaissance conducted during the nesting season on April 16, 2021. The closest known nesting record for Swainson's hawk as reported in the CNDDB is a nest site last active in 2008 (CNDDB Occurrence No. 1718) located approximately 2.1 miles north of the Project Site. Eucalyptus and other large trees located within about 0.25 miles from the Project Site provide potential nesting habitat.

Biologists with Monk & Associates conducted a formal nesting survey for Swainson's hawk for the Napa Logistics Project (adjacent property to the north of the Giovannoni site) in 2016/2017 using California Department of Fish and Wildlife's Swainson's hawk survey guidelines (CDFG 2000). Swainson's hawk nesting surveys were conducted April 5 and June 10, 2016 and

February 27, 2017 for all potential habitats within a mile of the project site for the Napa Logistics Phase II project, and no Swainson's hawks or evidence of any raptor nesting was observed within a zone of influence of the Project Site. HBG wildlife biologist Emilie Strauss conducted a similar survey for nesting Swainson's hawk for the Giovannoni Logistics Project on April 16, 2021. Ms. Strauss covered approximately 10 miles of local roads to inspect trees within approximately one mile from the Giovannoni Project Site and, again, no Swainson's hawk nests or any other raptor nests were found. Swainson's hawk has been known to nest in the area north of American Canyon and southwest of the City of Napa, and future nesting in suitable nest trees as close as about 0.5 miles from the Giovannoni Logistics Project Site cannot be ruled out.

Northern Harrier

Background. The northern harrier (*Circus hudsonius*) is a state species of special concern. Northern harriers build grass-lined nests on the ground within dense, low-lying vegetation in a variety of habitats, though they are typically found nesting in grassland or marsh habitats. They usually nest on level to near level ground. This species is particularly vulnerable to ground predators such as coyotes (*Canis latrans*), red fox (*Vulpes vulpes*), and various snake species. Ground nesting birds in general are also subject to disturbance by agricultural practices.

Occurrence in the Project Area. The 207.8-acre Project Site provides suitable foraging habitat for northern harrier both for wintering individuals and for individuals that may find suitable nesting sites in the project area. The 207.8-acres of open grasslands and seasonal wetlands over the Project Site also provide suitable nesting habitat for northern harrier. A wintering northern harrier was observed foraging over the site by HBG biologists during an HBG field review conducted on December 10, 2020, and a northern harrier was also observed foraging over the project site during the nesting season on April 16, 2021, suggesting that the species may nest somewhere in the project vicinity.

Golden Eagle

Background. The golden eagle (*Aquila chrysaetos)* is designated as a Bird Species of Conservation Concern by the USFWS and is also listed as a Fully Protected species in California. The golden eagle is also protected under the Bald and Golden Eagle Protection Act (16 U.S.C. 668-668c). Golden eagles are found breeding throughout western North America in remote open habitats. Typical habitats in North America include savannah woodland, grasslands, aspen parkland, high and low deserts, and taiga. Golden eagles feed on fresh carrion or take live prey ranging in size from small rodents to as large as newborn fawns. More typical prey includes rabbits, hares, and waterfowl. Golden eagles build nests in large trees, often eucalyptus, oaks, or conifers, or on large vertical cliffs. On rare occasions nests are found on the ground, especially in expansive prairie habitats where cliffs and/or trees are scarce. Often this species will return each year to the same nest site and reconstruct the existing nest structure. Golden eagles are very sensitive to disturbance near the nest site, particularly in remote regions where human activities are minimal.

Occurrence in the Project Area. There are no trees located on the 207.8-acre Project Site, and no large trees capable of supporting nesting by golden eagle in the immediate project vicinity, therefore it can be stated that golden eagle does not nest in the immediate vicinity of the Project Site. The non-native grasslands and seasonal wetlands and swales found on the property provide suitable foraging habitat for golden eagles that may nest away from the Project Site, as demonstrated by the presence of a foraging individual observed on the project site by an HBG biologist during a spring reconnaissance conducted on April 16, 2021. Eucalyptus and other large trees located within about 0.25 miles from the Project Site provide potential nesting habitat.

The closest known nesting record for golden eagle as reported in the CNDDB is a nest site (CNDDB Occurrence No. 82) located approximately 3.2 miles north of the Project Site in a eucalyptus tree surrounded by a vineyard. The CNDDB reports that this tree was cut down in 2008 and no longer provides a suitable golden eagle nest site. An additional nesting record is a nest site found by biologists with Monk & Associates approximately 4.5 miles east of the Project Site within the Newell Open Space within the City of American Canyon. This nest, also in a eucalyptus tree, was active in 2016 and 2017.

No nesting golden eagles (or nesting by any bird of prey species) were observed in large trees near the Project Site during formal nesting surveys for Swainson's hawk conducted by Monk & Associates in 2016/2017 for the Napa Logistics Project. Golden eagle was observed being harassed by Swainson's hawk and exhibiting foraging behavior over the Project Site during a spring survey by an HBG wildlife biologist on April 16, 2021. No nesting golden eagles were observed in the vicinity of the property during surveys for nesting Swainson's hawk conducted by biologists with HBG on that same date for the Giovannoni Logistics Project. As golden eagle has been known to nest in the general area of the City of American Canyon, future nesting in suitable nest trees as close as about 0.25 miles from the Project Site cannot be ruled out.

Burrowing Owl

Background. Burrowing owls (*Athene cunicularia*) are small terrestrial owls commonly found in open grassland ranging from western Canada to portions of South America. Burrowing owl habitat can be found in annual and perennial grasslands, deserts, and scrublands characterized by low-growing vegetation. In California, burrowing owls most commonly use burrows of California ground squirrel, but they also may use man-made structures, such as cement culverts; cement, asphalt, or wood debris piles; or openings beneath cement or asphalt pavement. Burrowing owls may use a site for breeding, wintering, foraging, and/or migration stopovers during migration. While foraging, owls will perch on raised burrow mounds or other topographic relief such as rocks, tall plants, fence posts, and debris piles to attain better visibility. Occupancy of suitable burrowing owl habitat can be verified at a site by an observation of at least one burrowing owl, or, alternatively, presence of "decoration" at or near a burrow entrance which can include molted feathers, cast pellets, prey remains, eggshell fragments, or excrement.

The burrowing owl is a USFWS bird species of conservation concern and a California Department of Fish and Wildlife (CDFW) species of special concern (CDFW 2011). CDFW adopted survey protocol and mitigation guidelines for burrowing owls as described in a March 7, 2012 Staff Report (CDFW 2012).

The status of burrowing owl in the San Francisco Bay Area was summarized by Albion Environmental (2000) in a discussion included in the SCVHP. Nesting burrowing owls in the greater San Francisco Bay Area, and in the South Bay area in particular, are a dwindling resource. In the early 1990s there were an estimated 150–170 breeding pairs in the San Francisco Bay Area, representing a 53% decline from the previous census period of 1986–1990. More recent numbers indicate that, if anything, the downward trend is increasing. In those estimates it was assumed that 75% of the San Francisco Bay Area burrowing owl population occurred in Santa Clara County and that nearly all of those owls were congregated around the southern edge of the San Francisco Bay.

Occurrence in the Project Area. The Project Site and surrounding area were investigated for burrowing owls and burrowing owl habitat during site reconnaissance by HBG biologists on December 10, 2020 and April 16, 2021. No burrowing owls were observed on the Project Site by HBG biologists during these field visits, and the only location supporting ground squirrels was an area noted in the rubble pile and compost at the perimeter of Clark's Rocks along Green Island Road that supported several ground squirrels in the spring of 2021. Dens of Botta's pocket gopher and California vole were common throughout the site, but these burrows are not suitable for occupation by burrowing owl. A general lack of ground squirrel burrows and ground squirrel colonies suggests that the habitat currently does not support burrowing owl and is currently not suitable to support burrowing owl.

No burrowing owls were reported at the site by other biologists who have studied the site over the last 5 years, including Monk & Associates (conducted brachiopod surveys and rare plant surveys on the property in 2016 through 2018), LSA Associates (conducted dry season brachiopod surveys in 2016), and Rana Resources (conducted a CRLF habitat assessment in 2021). A small number of burrowing owls have been recorded in the CNDDB within the general project vicinity, with the nearest reports from as close as about 1.7 miles north of the Project Site and about 2.5 miles south. Burrowing owls do not currently occur on the Project Site, but future occupation of the species on the property cannot be ruled out, especially if the property were to be occupied by a greater number of California ground squirrels.

Tricolored Blackbird

Background. Tricolored blackbird (*Aegelaius tricolor*) is listed as endangered under the California Endangered Species Act. Tricolored blackbird is also currently designated as a state species of special concern and is designated by the USFWS as a Bird Species of Conservation Concern. Tricolored blackbird is a highly colonial nesting species that breeds near freshwater, preferably in emergent wetlands with tall, dense growth of cattails or tules. Even when the preferred nesting substrates are available, other vegetation may be used for nesting including

sedges, nettles, willows, thistles, mustard, blackberry, wild rose, foxtail grass or barley. Since the 1970s with declines in populations, nesting in cereal crops and dairy silage has been documented. Tricolored blackbird foraging areas include rangeland, fields of alfalfa or cut hay, or irrigated pastures with an abundance of insects.

Occurrence in the Project Area. Tricolored blackbird has been known to occur in the vicinity of the Project Site. The nearest documented nesting colony to the Project Site is a colony of about 250 birds that nested in 1993 in two freshwater ponds vegetated with cattails, bulrush and willows located along Highway 29 just about 0.25 miles northeast of the northern border of the Project Site.

HBG conducted an evaluation of the habitat conditions at the proposed Project Site to determine if nesting substrate for a tricolored blackbird nesting colony is present in the project area. Preferred nesting habitat for tricolored blackbird was found not to be present as vegetation that typically provides suitable substrate for a tricolored blackbird nesting colony was not observed. Suitable tricolored blackbird nesting habitat typically consists of certain vegetation to include cattails, bulrushes, willows, blackberries, thistles, or nettles. As detailed in Section 4.4 (Plant Communities), dominant vegetation within the seasonal wetlands found on the property does not include a suite of species that would be conducive to tricolored blackbird nesting. Although sparse growth of some thistles and blackberries is present, few cattails, and no bulrushes, or willows, which are preferred nesting substrates, are present. Suitable nesting habitat for tricolored blackbird does not occur within the Project Site.

5.0 BIOLOGICAL IMPACTS AND MITIGATION MEASURES

5.1 Standards of Significance

The City of American Canyon's environmental review process pursuant to CEQA will evaluate the proposed Project east of Devlin Road with a Project Specific level of analysis based on site plans developed for the project, and the Phase 2 west of Devlin Road at a Program Level based on conceptual plans for the property if development were to occur in the future. The analysis for the proposed Project is independent from the Phase 2. When and if Phase 2 moves forward an addendum to the EIR will need to be conducted and the project will be re-evaluated based on the specifics and any new environmental or CEQA issues that will need to be assessed.

According to CEQA Guidelines (Appendix G), the project would be considered to have a significant impact on biological resources if it would:

a) Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Wildlife and Game or U.S. Fish and Wildlife Service.

b) Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the California Department of Fish and Wildlife or US Fish and Wildlife Service.

c) Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.

d) Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors or impede the use of native wildlife nursery sites.

e) Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

f) Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan.

5.2 Impacts and Mitigation Measures

1) Would the project have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service?

Special Status Plants

Although no special-status plants were identified on the Project Site by Monk & Associates while conducting various studies on the property in 2016, including an aquatic resources delineation and other evaluations conducted during the March to July flowering season of 2016, these studies did not constitute protocol surveys. A determination regarding whether special status plant species are present in proposed development areas can only be made based on systematic rare plant surveys conducted during the flowering period of target plant species. Therefore, HBG has retained Dr. Brent Helm to conduct protocol rare plant surveys during the 2021 flowering season. These surveys are currently underway, and a special status plant survey report is expected to be completed by July of 2021.

Impact 1: If protocol surveys show that special status plant species are present in areas of proposed development, impacts to populations of rare (special status) plants are possible.

> **Mitigation Measure 1-1:** If protocol rare plant surveys conducted during the spring and summer of 2021 show special status plant species are present within or in close proximity to areas of proposed development, mitigation to conserve and/or protect populations of rare plants may be warranted. Such mitigation measures could include avoidance of rare plant populations in the design of project development, and if avoidance of populations is not possible, mitigation measures could require transplanting of plants or development of plans to recover seeds and establish populations to nearby suitable habitats within the approximately 44.8-acre Wetland Preserve.

Special Status Animals

Monarch Butterfly. No trees are present on the Project Site so there is no possibility for the presence of a monarch overwintering site at the site. Several biologists have studied the site or portions of the site, and none have reported the presence of milkweed plants of the genus *Asclepias* that serve as the larval host plant for monarchs. No suitable habitat for monarch butterflies is found on the site, therefore, no potentially significant impacts to monarch butterflies would result from construction of the Giovannoni Logistics Center Project or any future development within a Phase 2.

Vernal Pool Fairy Shrimp. Based on completed protocol surveys for vernal brachiopods (LSA 2016, Monk & Associates 2017), it is clear that the federally listed threatened vernal pool fairy

shrimp does not occur on the Project Site. Therefore, no impacts to vernal pool fairy shrimp would result from construction of the proposed project. No mitigation is warranted for vernal pool fairy shrimp for either the Giovannoni Logistics Center Project or any future development for a Phase 2.

California Red-legged Frog. A protocol Habitat Assessment prepared for the Project Site by Rana Resources found that the Project Site lacks habitat necessary to support CRLF. All records of CRLF from the CNDDB in the project area are from areas east of Highway 29, which forms a barrier to potential movements of CRLF onto the site. Additionally, the Project Site is completely isolated from all areas to the east by Highway 29 by urban infrastructure, and there are no hydrologic connections with any stream channels off-site to the east of Highway 29. Finally, there is no suitable breeding or rearing habitat for CRLF on site due to the shallow and ephemeral nature of the seasonal wetlands and the lack of any suitable riparian vegetation for cover. CRLF do not occupy the Project Site, and the proposed Project would have no significant impacts on California red-legged frogs. No mitigation is warranted for this species for either the Giovannoni Logistics Center Project or any future development for a Phase 2.

Western Pond Turtle. Suitable habitat for western pond turtle does not occur on the site due to the shallow and ephemeral nature of the seasonal wetlands, which are inundated for only about 3 to 4 months out of the year and even less in drought years. Surrounding uplands of suitable shrub/woodlands and appropriate basking sites are also lacking. Western pond turtle does not occupy the Project Site. No impacts to western pond turtle would result from development of the Project. Mitigation measures for western pond turtle are not warranted for either the Giovannoni Logistics Center Project or any future development for a Phase 2.

Swainson's Hawk. There are no trees located on the Project Site, and no large trees capable of supporting nesting by Swainson's hawk in the immediate project vicinity, however, the non-native grasslands and seasonal wetlands and swales found on the property provide suitable foraging habitat for Swainson's hawks that may nest away from the Project Site. Swainson's hawk was observed foraging on the site in spring 2021. Development of the Project will remove some foraging area for this species, but the establishment of the 44.8-acre Wetland Preserve will preserve a 44.8-acre area of suitable Swainson's hawk foraging habitat into perpetuity. Although eucalyptus and other large trees located within about 0.25 miles from the Project Site provide potential nesting habitat, no nesting by Swainson's hawk (or any raptor species) was noted during surveys for nesting Swainson's hawk conducted by HBG in April of 2021.

If an active Swainson's hawk nest is found on or adjacent to the Project Site or within the area of influence of the Project Site (which is generally considered to be within 1,000 feet), CDFW could require that project-related disturbance at active nest sites be reduced or eliminated during the period from March 1- September 15 (CDFW 2000). If Swainson's hawk was found to be nesting within a zone of influence during the construction period, potential impacts to this species could occur, including disturbance to nesting birds and possible mortality of adults and/or young. If nest disturbances are anticipated to occur, a Fish and Game Section 2081 management

authorization would be required. Preconstruction nesting surveys are warranted for either the Giovannoni Logistics Center Project or for any future development of a Phase 2 to ensure that the proposed Project will not impact this hawk species.

Impact 2: Project construction could impact nesting Swainson's hawk if individuals of this species were found to be nesting within 1,000 feet of project construction.

> **Mitigation Measure 2-1:** The mitigation measure for the possibility of nesting Swainson's hawk in the project vicinity should be as required by Monk & Associates (2018) in the Biological Resources Analysis for the Devlin Road/Vine Trail Extension Project, included (Appendix C of the Initial Study/Proposed Mitigated Negative Declaration for the project) and for the Biological Resources Analysis for the Green Island Road Reconstruction and Widening Project (Monk 2019) (Appendix C of the Initial/Study Proposed Mitigated Negative Declaration for the project) as summarized below:
>
> Preconstruction surveys for Swainson's hawk shall be conducted in the Project Site vicinity prior to initiation of project construction activities. These preconstruction surveys should include investigation of all potential nesting trees within a half-mile radius around all project activities and shall be completed for at least two survey periods immediately prior to commencement of Project construction. Surveys should follow CDFW guidelines for conducting surveys for Swainson's hawk (CDFW 2000) that were developed by the Swainson's Hawk Technical Advisory Committee to maximize the potential for locating nesting Swainson's hawks and reduce the potential for nest failures as a result of project activities and/or disturbances.
>
> If Swainson's hawks are found to be nesting within 1,000 feet of the project site, the applicant shall consult with CDFW to determine if a Fish and Game Section 2081 management authorization shall be obtained from CDFW. A nest site buffer shall be established in consultation with the CDFW or as required in any Fish and Game Section 2081 management authorization issued to the project by the CDFW. An established buffer zone of a minimum of 500 feet from a nest site would be typical. The nest protection buffer shall be maintained until the Swainson's hawk nesting attempt is completed as determined by a qualified biologist.

Golden Eagle. There are no trees located on the Project Site, and no large trees capable of supporting nesting by golden eagle in the immediate vicinity of the Project Site, however, the non-native grasslands and seasonal wetlands and swales found on the property provide suitable foraging habitat for golden eagles that may nest away from the Project Site. Golden eagle was observed exhibiting foraging behavior on the site in spring 2021. Although eucalyptus and other large trees located within about 0.25 miles from the Project Site provide potential nesting habitat, no nesting by golden eagle (or any raptor species) was noted during surveys for nesting Swainson's hawk conducted by HBG in April of 2021.

As golden eagle has been known to nest in the general area of the City of American Canyon, future nesting in suitable nest trees as close as about 0.25 miles from the Giovannoni Logistics Project Site cannot be ruled out. If a golden eagle were found to be nesting within a zone of influence of the project during the construction period, potential impacts to this species from the proposed project could occur, including disturbance to nesting birds and possible mortality of adults and/or young. Preconstruction surveys for golden eagle are warranted for either the Giovannoni Logistics Center Project or for any future development of a Phase 2 to ensure that construction activities do not result in impacts to nesting individuals of this species. With a requirement of preconstruction surveys, a potentially significant impact on golden eagle could be mitigated to a level considered less than significant.

Impact 3: Project construction could impact nesting golden eagle if individuals of this species were found to be nesting in the vicinity of project construction.

> **Mitigation Measure 3-1:** The mitigation measure for the possibility of nesting golden eagle in the project vicinity should be as required by Monk & Associates (2018) in the Biological Resources Analysis for the Devlin Road/Vine Trail Extension Project, included as Appendix C of the Initial Study/Proposed Mitigated Negative Declaration for the project as summarized below:
>
> Preconstruction golden eagle nesting surveys shall be conducted in the Project Site vicinity within 30 days of initiation of project construction activities. Preconstruction surveys should include investigation of all potential nesting trees within a half-mile radius around all project activities. If active nests of golden eagles are identified within eucalyptus trees or any other trees within a 0.5-mile radius of the project site, a qualified raptor biologist will establish a protection buffer that is adequate to ensure that noise or activity from the project would not cause nest disturbance or mortality of young birds or adults. Buffer zones may be variable in size as some golden eagles are more acclimated to disturbance than others. Size of buffer zone could be modified in consultation with CDFW considering behavioral factors and the extent that golden eagles may have acclimated to disturbance. No construction or earth-moving activity shall occur within the established buffer zone until it is determined by a qualified raptor biologist that the young golden eagles have fledged or that the nesting cycle is otherwise determined to be complete based on monitoring of the active nest by a qualified biologist.

Northern Harrier. Suitable nesting habitat for the northern harrier (a state designated species of special concern) occurs within the non-native grasslands and seasonal wetlands and swales found within the Project Site. Northern harrier individuals were observed foraging over the Project Site during both winter and spring (breeding) seasons during surveys conducted by HBG. If a northern harrier were found to be nesting on the Project Site during the construction period, potential impacts to this species from the proposed project could occur, including disturbance to nesting birds and possible mortality of adults and/or young. Nesting by northern harrier has not been documented on the Project Site, but nesting by this species at the site is possible.

Preconstruction surveys for northern harrier are warranted for either the Giovannoni Logistics Center Project or for any future development of a Phase 2 to ensure that construction activities do not result in impacts to nesting individuals of this species.

Impact 4: Construction of the proposed project could result in disruption of northern harrier nesting if the species were found to be nesting during the construction period.

> **Mitigation Measure 4-1:** The mitigation measure for the possibility of nesting Northern harrier in the project vicinity should be as required in the Biological Resources Analysis for the Devlin Road/Vine Trail Extension Project (Monk 2018)(Appendix C of the Initial Study/Proposed Mitigated Negative Declaration for the project) as summarized below:
>
> Prior to ground disturbance, a preconstruction nesting survey shall be conducted for northern harrier if construction is scheduled during the nesting season (February 1 through September 1). To determine if northern harrier is nesting onsite, a qualified raptor biologist(s) shall conduct walking transects through the Project Site grassland habitat searching for nests. An active northern harrier nest must be protected by implementing a suitable 500-foot radius buffer zone around the nest marked with orange construction fencing. If an active nest is located outside of the Project Site, the buffer should be extended onto the Project Site and demarcated where it intersects the Project Site. Size of buffer zone could be modified in consultation with CDFW considering behavioral factors and the extent that northern harriers may have acclimated to disturbance. No construction or earth-moving activity shall occur within the established buffer zone until it is determined by a qualified raptor biologist that the young have fledged or that the nesting cycle is otherwise determined to be complete based on monitoring of the active nest by a qualified biologist.

Burrowing Owl. A small number of burrowing owls have been recorded in the CNDDB within the general project vicinity, with the nearest reports from as close as about 1.7 miles north of the Project Site and about 2.5 miles south. No burrowing owls or occupied California ground squirrel burrows were observed on the Project Site during a field reviews conducted by HBG in December 2020 and April 2021 or during previous biological studies conducted by Monk & Associates, LSA Associates or Rana Resources. The only observed ground squirrels were from the area around the perimeter of Clark's Rocks. It remains possible that ground squirrels could establish colonies on the site in the future prior to project construction, providing new occupiable habitats for burrowing owl. Future use of the site by burrowing owl cannot be ruled out.

Impact 5: Project construction could impact burrowing owl if California ground squirrels were to occupy the site in the future, providing occupiable sites for wintering or nesting by burrowing owl. The following mitigation measure would ensure that no burrowing owls would be impacted by construction activities associated with either the Giovannoni Logistics Center Project or for any future development of a Phase 2.

Mitigation Measure 5-1: Pre-construction surveys for burrowing owls shall be conducted prior to any ground-disturbance to ensure that there are no impacts to burrowing owls. The pre-construction surveys will be conducted within two weeks prior to the onset of any ground disturbing activities. Surveys will be conducted by a qualified biologist following CDFW survey methods (CDFW 2012) to establish the status of burrowing owl on the Project Site.

- If burrowing owls are found to occupy the Project Site during the non-breeding season (September 1 to January 31), occupied burrows will be avoided by establishing a no-disturbance buffer zone around the burrow determined per the CDFW 2012 staff report. If avoidance is not possible a passive relocation effort may be instituted to relocate the individual(s) out of harm's way pursuant to a Burrowing Owl Exclusion Plan prepared in accordance with the CDFW 2012 staff report.

- If burrowing owls are found to be present during the breeding season (February 1 to August 31), the project ground disturbing activities will follow the CDFW recommended avoidance protocol whereby occupied burrows will be avoided with a no-disturbance buffer.

Tricolored Blackbird. No impact to tricolored blackbird nesting colonies would occur as a result of the proposed project. Although tricolored nesting colonies have been documented about 0.25 miles from the Project Site as recently as 1993, HBG has concluded that vegetative characteristics of preferred nesting habitat for tricolored blackbird does not occur at the Project Site. Suitable nesting habitat for tricolored blackbird does not occur within the Project Site, therefore, no impacts to tricolored blackbird nesting colonies would result from implementation of the proposed project.

2) Would the project have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, or regulations or by the California Department of Fish and Wildlife or US Fish and Wildlife Service?

The proposed Project development east of Devlin Road would impact approximately 0.496-acres of palustrine emergent wetlands. If or when Phase 2 west of Devlin Road is developed, approximately 3.7-acres of palustrine emergent wetlands may be impacted. Plans for wetland mitigation, including the preservation of an approximately 44.8-acre Wetland Preserve to include existing wetlands as well as established/created wetlands intended to offset wetland impacts of buildout development of the Project Site, are discussed in response to Item #3.

The portion of the Project Site along the northern boundary contained within the confines of No Name Creek would be subject to the regulatory jurisdiction of the CDFW under Fish and Game Code Section 1602. As the area of No Name Creek is contained within the approximately

44.8-acre Wetland Preserve, no impacts to the palustrine emergent wetland swale associated with No Name Creek would occur from either the proposed Project in the area east of Devlin Road or any possible future development that might occur within Phase 2 in the area west of Devlin Road. No impacts would occur to areas that would be subject to CDFW jurisdiction under Fish and Game Code Section 1602, therefore, there would be no requirement to obtain a Streambed Alteration Agreement from CDFW.

3) Would the project have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?

Wetland Impacts. Development of the proposed Project within the area east of Devlin Road will result in impacts to wetlands subject to USACE jurisdiction as a Water of the U.S. (WOUS) and subject to SFBRWQCB jurisdiction as a Water of the State (WOS). Grading activities associated with the proposed Project would result in the permanent placement of fill material (soil) into 0.496 acres of palustrine emergent wetlands considered WOS. Of this 0.496 acres of impacts to WOS, the USACE has determined 0.492 acres are isolated and not considered WOUS. Therefore, the proposed Project will also impact 0.004 acres of palustrine emergent wetlands considered WOUS. The location of wetland impacts associated with development of the proposed Project in the area east of Devlin Road is shown in Figure 5. The City of American Canyon processed a separate Nationwide Permit for impacts to 0.21 acres on the 8.3-acre Project Site for the Devlin Road/Vine Trail Extension project.

An enumeration of the wetland impacts within the proposed Project development is detailed in Table 2.

Table 2. Wetland Impacts

Isolated Wetland (IW)	**Square Feet / Acres**
IW-2	97 / 0.002
IW-3	229 / 0.005
IW-4	3117 / 0.072
IW-5	17019 / 0.391
IW-6	935 / 0.022
USACE Jurisdictional Wetlands	
W-89	189 / 0.004
Total	**21,586 / 0.496**

These wetland impacts will require that the applicant apply for and obtain a Nationwide Permit from USACE for discharge within 0.004 acres of wetlands under Clean Water Act Section 404 jurisdiction. A plan to compensate for impacts to wetlands would also be required. In addition, an accompanying Section 401 Water Quality Certification from the SFBRWQCB would be

required for the USACE permit to be valid. Such a project would also require a separate Waiver of Waste Discharge from the SFBRWQCB for impacts to 0.496 acres of waters of the state.

If the applicant were to pursue a similar warehouse logistics center development as a second phase of development on the remaining 85.9 acre area on the west side of the Devlin Road Extension, such a development would impact up to approximately 3.7 acres of wetlands considered both WOUS and WOS, assuming buildout of Phase 2. The location of these wetland impacts is shown in Figure 6. A project impacting more than 0.5 acres of wetlands would require an Individual Permit rather than Nationwide Permit from USACE. Impacts to wetlands totaling 3.7 acres for a possible Phase 2 project in the future would require that the applicant submit a separate application for an Individual Permit from USACE. The application would require a plan to compensate for wetland losses as well as a detailed alternatives analysis under the Section 404(b)(1) guidelines. Such a development on the Phase 2 portion of the Project Site would also require a Clean Water Act Section 401 Water Quality Certification from the SFBRWQCB for the USACE permit to be valid and would also require a Waiver of Waste Discharge Requirements from SFBRWQCB pursuant to the Porter-Cologne Water Quality Control Act.

Wetland Mitigation and Monitoring Plan. As part of this Project an approximately 44.8-Acre Wetland Preserve fronting the northern boundary of the Project Site will be preserved. This Wetland Preserve supports 7.71 acres of the palustrine emergent wetlands out of the existing 12.77 acres of wetlands found on the entirety of the Project Site. Within the Wetland Preserve, the applicant intends to create approximately 0.992 acres of wetlands to offset wetlands impacts of the proposed Project (0.496 acres) at a 2:1 ratio, and to create and an additional 3.7-acres of wetlands that will offset wetlands impacts associated with possible development of a Phase 2 project at a 1:1 ratio. Wetlands created within the Wetland Preserve would include 0.992 acres of wetland mitigation to compensate for wetlands impacts of the proposed Project in the area east of Devlin Road and approximately 3.7 acres of wetland mitigation to compensate for wetland impacts of a potential Phase 2 in the area west of Devlin Road. If additional wetland mitigation lands are required to compensate for wetland impacts associated with Phase 2, wetlands will be created on appropriate mitigation land, approved by the RWQCB and USACE, within the Phase 2 project site's HUC 10 watershed. Wetlands created to compensate for an eventual Phase 2 project would be constructed and monitored with performance standards prior to the implementation of Phase 2 and incorporated into the Wetland Mitigation and Monitoring Plan associated with the Project and protected in perpetuity. This will allow for the created wetlands to establish and function as wetlands and be protected prior to project development of Phase 2, if such development were to happen at all. This allows Phase 2 to provide a 1:1 mitigation ratio compared to the proposed Project which is establishing/creating wetlands concurrent with Project development and therefore must account for temporal loss of wetland functions and values as the wetlands develop over time.

Wetlands created within the approximately 44.8-acre Wetland Preserve as part of the Mitigation Plan would total approximately 4.7 acres of created wetlands. Figure 9 shows a

Wetland Mitigation Site Plan for the general location of the 44.8-acre Wetland Preserve in relation to the Project Site as well as the location of proposed mitigation wetlands in relation to existing wetlands.

A conceptual Wetland Mitigation and Monitoring Plan (Plan) is described herein to compensate for the loss of 0.496 acres of wetlands as a result of implementing the proposed Project in the area east of Devlin Road as shown on Figure 5, and a detailed Plan will be prepared and submitted to the SFBRWQCB for review as part of the process for obtaining a permit from this agency. In addition, the Plan will address the approximate impact to 3.7 acres of wetlands that may occur in the future as part of a Phase 2, assuming Phase 2 is built out. The approximately 44.8 acres of open space on the east and west side of Devlin Road would be preserved to create a contiguous open space area with the adjoining 37-acre Napa Logistics Park wetland preserve. The Plan will include a site protection instrument (e.g., deed restriction or conservation easements) that will restrict use of the Wetland Preserve area to offset wetland impacts for both the 0.992 acres of created wetlands for the proposed Project as well as the created approximately 3.7 acres of additional wetlands for a potential Phase 2 project. Regardless of whether or not Phase 2 is implemented, a long-term endowment would be fully funded by the proposed Project to manage the entire 44.8-acre open space preserve and both existing and created wetlands in perpetuity.

The Plan will be prepared in accordance with the Subpart J – Compensatory Mitigation for Losses of Aquatic Resources outlined in the State Water Resources Control Board Procedures, and in accordance with the State Water Resources Control Board *Implementation Guidance* dated April 2020. The basic objective of the Plan is to ensure that the project wetland impacts, and compensatory mitigation proposed to offset the wetland impacts, will provide an increase in the overall abundance of wetlands (e.g. increase in acreage), and the created wetlands will have an overall increase in plant diversity and structural complexity compared to the wetlands that will be filled. The purpose is to ensure the Plan offsets the permanent wetland impacts, and any temporal loss of function attributed to the Project and future Phase 2 development, assuming Phase 2 is built out. In summary, the Plan will:

1. Establish within the Wetland Preserve 0.992 acres of palustrine emergent wetlands in advance of or concurrent with implementation of Project impacts to 0.496 acres of palustrine emergent wetlands at a 2:1 ratio.
2. Establish within the Wetland Preserve approximately 3.7 acres of palustrine emergent wetlands in advance of implementation of future Phase 2, assuming Phase 2 is built out, to address the potential maximum losses of approximately 3.7 acres of wetlands that may occur. If additional wetland mitigation lands are required to compensate for wetland impacts associated with Phase 2, wetlands will be created on appropriate mitigation land, approved by the RWQCB and USACE, within the Phase 2 project site's HUC 10 watershed.

3. In select areas, install native trees and shrubs to enhance the upland buffer areas adjacent to the established wetlands. The site is lacking vertical biotic structure likely due to past grazing activities. As part of the Plan, native trees and shrubs will be planted in select areas to enhance the upland buffer areas adjacent to established and existing wetlands.
4. Provide financial assurances to ensure a high level of confidence that the compensatory mitigation will be successfully completed, in accordance with applicable performance standards.
5. Design ecological performance standards to assess whether the Plan is achieving the overall objectives, so that it can be objectively evaluated to determine if it is developing into the desired resource type, providing the expected conditions or function, and attaining any other applicable metrics such as acres, percent cover of native plants, structural patch richness, control of invasive plants, water depth etc.
6. Monitor the site for a duration necessary to determine if the Plan is meeting the performance standards. Established palustrine emergent wetlands typically develop quickly and a 5 year monitoring period would be sufficient to determine if performance standards are met. This monitoring period may be extended if performance standards are not met due to how the wetlands were constructed or natural events such as severe droughts.
7. Protect the approximately 44.8 acre Wetland Preserve in perpetuity using a site protection instrument such as a deed restriction or conservation easement, and provide an endowment sufficient to fund the Long-Term Management Plan; and
8. Assess the potential effects of changing weather patterns that are currently occurring, and that may occur due to climate change in the foreseeable future and how these changes may impact the long-term viability of the constructed wetlands. The purpose of this assessment is to locate and design the wetlands to avoid and minimize impacts from climate change and to develop adaptive management measures into the Plan specifically to minimize these potential effects.

The Plan will include a watershed profile of the evaluation area which, for the purpose of this Project, will encompass the approximate watershed area of No Name Creek. In addition, an overall assessment of the condition of the wetlands that will be filled by the Project will be conducted. Using the California Rapid Assessment Method (CRAM) for depressional wetlands, or a hybrid approach based on CRAM, each similar wetland type that may be impacted will be assessed to describe and measure the plant community/diversity composition, hydrology source and connectivity within the watershed, physical structure such as topographic complexity and physical features that may provide habitat for aquatic species, plant zones within the wetlands, maximum water depth, and stressors that may be indirectly affecting the wetlands that will be filled by the Project. The purpose of this assessment is to ensure the design of the wetlands will provide a similar or more complex and diverse habitat as the

wetlands prior to being filled and to ensure the performance standards proposed in the Plan will be able to measure the success of the newly established wetlands.

Impact 6: Grading activities would result in the permanent placement of fill material (soil) into 0.496 acres of palustrine emergent wetlands considered WOS under the Porter-Cologne Water Quality Control Act. Of the 0.496 acres of WOS, the USACE has determined 0.492 acres are isolated and not considered WOUS under the federal Clean Water Act, so the proposed Project would also impact the remaining 0.004 acres of palustrine emergent wetlands considered WOUS. These impacts will require that the applicant apply for and obtain a Nationwide Permit from USACE for discharge within 0.004 acres of wetlands under Clean Water Act Section 404 jurisdiction along with an accompanying Section 401 Water Quality Certification from the SFBRWQCB. The applicant will also need to apply for and obtain a separate Waiver of Waste Discharge from the SFBRWQCB for impacts to 0.496 acres of Waters of the State.

> **Mitigation Measure 6-1**: The Project applicant for the proposed Giovannoni Logistics Center Project will apply for and obtain a Nationwide Permit from the San Francisco District of USACE for discharge within 0.004 acres of wetlands/Waters of the U.S. under Clean Water Act Section 404 jurisdiction. For the USACE permit to be valid, the applicant will apply for and obtain the accompanying Section 401 Water Quality Certification from the SFBRWQCB. The applicant will apply for and obtain a separate Waiver of Waste Discharge Requirements from the SFBRWQCB for impacts to 0.496 acres of waters of the state.
>
> **Mitigation Measure 6-2:** A detailed Wetland Mitigation and Monitoring Plan will be prepared and submitted to the SFBRWQCB for review as part of the process for obtaining a permit from the agency. The Wetland Mitigation and Monitoring Plan will address the loss of 0.496 acres of wetlands impact due to the proposed Project as well as the potential loss of approximately 3.7 acres of wetlands that may occur in the future as part of a Phase 2, assuming Phase 2 is built out. The Wetland Mitigation and Monitoring Plan will include a site protection instrument (e.g., deed restriction or conservation easements) that will restrict use of both the 0.992 acres of created wetlands for the proposed Project as well as approximately 3.7 acres of additional wetlands created for a potential Phase 2 project. The Wetland Mitigation and Monitoring Plan will also include a long-term endowment that would be fully funded by the proposed Project to manage approximately 44.8-acre open space preserve and created wetlands in perpetuity. If additional wetland mitigation lands are required to compensate for wetland impacts associated with Phase 2, wetlands will be created on appropriate mitigation land, approved by the RWQCB and USACE, within the Phase 2 project site's HUC 10 watershed.

Impact 7: If the applicant were to pursue a development within the Phase 2 area, such a development would impact approximately 3.7 acres of wetlands considered both WOUS and WOS, assuming buildout of Phase 2. Impacts to approximately 3.7 acres of wetlands for a

possible Phase 2 project would require that the applicant submit a separate application for an Individual Permit from USACE to include a plan to compensate for wetland losses as well as a detailed alternatives analysis under the Section 404(b)(1) guidelines to include a detailed evaluation of both onsite and offsite alternatives for the proposed project. Such a development on the Phase 2 portion of the Project Site would also require a Clean Water Act Section 401 Water Quality Certification from the SFBRWQCB for the USACE permit to be valid and would also require a Waiver of Waste Discharge Requirements for SFBRWCB pursuant to the Porter-Cologne Water Quality Control Act.

> **Mitigation Measure 7-1**: The project applicant for a future development in the Phase 2 area west of Devlin Road will apply for and obtain an Individual Permit from the San Francisco District of USACE for the placement of fill material within approximately 3.7 acres of wetlands/Waters of the U.S. under Clean Water Act Section 404 jurisdiction. For the USACE permit to be valid, the applicant will apply for and obtain the accompanying Section 401 Water Quality Certification from the SFBRWQCB. The applicant will apply for and obtain a separate Waiver of Waste Discharge Requirements from the SFBRWQCB for the discharge of fill material within approximately 3.7 acres of Waters of the state.

4) Would the project interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?

Although a number of wildlife species, including a variety of bird species that potentially include special status species, were observed on the property during field surveys, neither the development of the proposed Project nor potential development of a future Phase 2 project would result in significant impacts to wildlife populations on the site. Mitigation measures to address impacts to sensitive habitats, most notably seasonal wetlands, are included herein that include the preparation and implementation of a detailed Compensatory Wetland Mitigation Plan. The site design includes the preservation of the approximately 44.8-acre Wetland Preserve that will preserve 7.71 acres of existing wetlands but will also include creation of approximately 4.7 additional wetland acres. Potential impacts to special status avian species will be mitigated as the applicant for either the proposed Project or future potential development of a Phase 2 is required herein to conduct preconstruction surveys for nesting by special status bird species including Swainson's hawk, golden eagle, northern harrier, and burrowing owl.

Any species of fauna that may be displaced during preparation of the site for development of the proposed Project or the possible development of a Phase 2 project should find nearby available habitats, including habitats within the approximately 44.8-acre Wetland Preserve or adjacent and contiguous 37-acre preserve for the Napa Logistics Project on the adjacent property. The major wildlife corridor along No Name Creek will remain unaffected as the entirety of No Name Creek will be incorporated into the Wetland Preserve. The project will not result in substantial change in animal populations at the site, nor will it cause a fish or wildlife population to drop below self-sustaining levels.

Nesting Birds. Nesting bird species protected by the federal Migratory Bird Treaty Act or California Fish and Game Code could be impacted during project construction. Work related to construction involving the removal of vegetation during the February 1 to August 1 breeding season of birds could result in mortality of nesting avian species if they are present. Many species of raptors (birds of prey) are sensitive to human incursion and construction activities, and it is necessary to ensure that nesting raptor species are not present in the vicinity of construction sites.

To ensure compliance with the MBTA and the California Fish and Game Code, bird nesting surveys are generally required if construction work requires vegetation removal during the bird nesting season. CDFW generally considers the nesting season to be from February 1 to August 31 for most bird species. Required setbacks to protect active nests from construction activity are usually in the order of about 250 feet for passerines (songbirds) and 500 feet or more for raptors (birds of prey).

Habitats within the Project Site were shown to support a number of bird species during field surveys conducted in the winter and spring of 2021 by HBG. The onsite grasslands and seasonal wetlands provide suitable nesting substrate for a number of species. Many of the bird species documented on or near the site as described in Section 4.4 could possibly nest within the vegetation in the onsite grasslands or seasonal wetlands. If active nests were present in this vegetation during construction operations on the Project Site, direct or indirect impacts could occur to nesting bird species protected by the Migratory Bird Treaty Act or the California Fish and Game Code as a result of construction activity.

Impact 8: The removal of vegetation during the February 1 to August 31 breeding season, either for the proposed Project or for a potential future Phase 2 development, could result in mortality of nesting avian species if they are present.

> **Mitigation Measure 8-1:** If construction is to be conducted during the breeding season of migratory birds (February 1 to August 31), a qualified biologist should conduct a pre-construction breeding bird survey in areas of suitable habitat within 15 days prior to the onset of construction activity. Nesting bird surveys should cover the project footprint and adjacent areas. If bird nests are found, appropriate buffer zones should be established around all active nests to protect nesting adults and their young from direct or indirect impacts related to project construction disturbance. Size of buffer zones should be determined per recommendations of the qualified biologist based on site conditions and species involved. Buffer zones should be maintained until it can be documented that either the nest has failed, or the young have fledged.

Water Quality. Construction activities for the proposed project will occur in within 0.496 acres of wetlands subject to State jurisdiction and in close proximity to areas within the upper reaches of No Name Creek, but water quality impacts to these features would not be significant

for several reasons. The requirement for the implementation of a Stormwater Pollution Prevention Plan (SWPPP), with identification of proper construction techniques and Best Management Practices (BMPs) will be required and will provide assurance that water quality of nearby waterways is not affected by onsite construction activities. In particular, silt fence and straw wattles will be installed along portions of the Project Site to maintain levels of water pollutants migrating offsite. In addition, vegetation will only be cleared from the permitted construction footprint. Areas cleared of vegetation, pavement, or other substrates should be stabilized as quickly as possible to prevent erosion and runoff. These requirements would be germane to any development for the proposed Project or for potential development of a Phase 2 west of Devlin Road.

Grading, excavation, placement of fill material, and other ground-disturbing activities associated with construction activities within the Project Site will not promote erosion that would allow elevated levels of sediment to wash into aquatic areas downstream, including No Name Creek, where such pollutants could result in potential impacts to fish and wildlife resources. Indirect impacts to resident animal populations in downstream areas would not result from the proposed project due to elevated turbidity levels from increased sedimentation or increases in other contaminants in stormwater runoff.

5) Would the project conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?

The Project would not conflict with any local policies related to protection of natural resources. No trees are present on the Project Site so no trees would need to be removed to accommodate either the proposed Project or any future development within Phase 2.

All work for the Project would take place consistent with biological requirements of the General Plan and Zoning Ordinance of the City of American Canyon. This Biological Resources Report provides the detailed assessment of biological resources required by General Plan Policies 8.1.1 and 8.1.4. Studies of sensitive biological resources have been either conducted by HBG as part of this Biological Resources Report or were conducted by other consultants and independently reviewed and incorporated into the Biological Resources Report, consistent with General Plan Policy 8.2.1. Studies conducted by HBG include a protocol Phase 1 Habitat Assessment for the federally listed threatened California red-legged frog, surveys for state listed threatened Swainson's hawk and rare plant surveys, currently underway, by Dr. Brent Helm during the 2021 flowering season. Studies conducted by others include wet and dry season protocol surveys for the federally listed threatened vernal pool fairy shrimp and rare plant surveys. The proposed project results in impacts to seasonal wetlands and the applicant has prepared a conceptual plan to mitigate for these wetlands consistent with General Plan Policies 8.3.1.a, 8.3.1.h and 8.4.3. The wetland mitigation would be accomplished through establishment of an approximately 44.8-acre Wetland Preserve within the Project Site to include 7.71 acres of existing wetlands and creation of an additional 4.7 acres of seasonal wetlands to compensate for onsite losses from the proposed Project and from a potential future development project within Phase 2.

6) Would the project conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?

The project site is not within an area where the provisions of a Habitat Conservation Plan or Natural Community Conservation Plan would apply.

TABLES

Table 1. Plants Species Observed on the Project Site

Table 2. Special Status Plants with Potential to Occur in the Vicinity of the Project Site, City of American Canyon, California

Table 3. Special Status Animal Species that Have Been Reported in the Vicinity of the Project Site, City of American Canyon, California

Table 4. Table 2 & 3 Status Code Definitions

Table 1. Plant Species Observed on the Project Site[2]	
Family/Genius[3]/Species/Subspecies	**Common Name**
DICOTS	
Apiaceae	
Eryngium aristulatum var. aristulatum	California coyote-thistle
*Foeniculum vulgare	Sweet fennel
Perideridia kelloggii	Kellogg's yampah
Asteraceae	
Agoseris grandiflora	giant mountain dandelion
**Anthemis cotula*	Mayweed
Baccharis pilularis subsp. consanguinea	Coyote brush
**Calendula arvensis*	Field-marigold
**Carduus pycnocephalus subsp. pycnocephalus*	Italian thistle
**Centaurea calcitrapa*	Purple starthistle
**Centaurea solstitialis*	Yellow starthistle
**Cichorium intybus*	Chicory
**Cirsium vulgare*	Bull thistle
**Cotula coronopifolia*	Brass-buttons
Deinandra corymbosa	Coast tarweed
**Helminthotheca echioides*	Bristly ox-tongue
Hemizonia congesta subsp. luzulifolia	White hayfield tarweed
**Hypochaeris radicata*	Rough cat's-ear
**Lactuca saligna*	Willow lettuce
**Lactuca serriola*	Prickly lettuce
Lasthenia glaberrima	Smooth goldfields
**Leontodon saxatilis subsp. longirostris*	Long-beaked hawkbit
Microseris douglasii subsp. douglasii	Douglas' silverpuffs
**Pseudognaphalium luteoalbum*	Everlasting cudweed
Psilocarphus brevissimus var. brevissimus	Dwarf woolly-heads
**Senecio vulgaris*	Common groundsel
**Sonchus asper subsp. asper*	Prickly sow-thistle
**Sonchus oleraceus*	Common sow-thistle
**Taraxacum officinale*	Common dandelion
**Tragopogon porrifolius*	Common salsify
Boraginaceae	
Plagiobothrys stipitatus var. micranthus	Great Valley popcornflower
Plagiobothrys undulatus	Wavy-stemmed popcornflower
Brassicaceae	
**Brassica nigra*	Black mustard

[2] List includes Angiosperms only.

[3] * Denotes California native species.

Table 1. Plant Species Observed on the Project Site[2]	
Family/Genius[3]/Species/Subspecies	**Common Name**
**Brassica rapa*	Field mustard
Cardamine californica	Milk maids
**Lepidium latifolium*	Broadleaf pepperweed
**Nasturtium officinale*	Water cress
**Raphanus raphanistrum*	Jointed charlock
**Raphanus sativus*	Wild radish
**Sisymbrium altissimum*	Tumble mustard
Campanulaceae	
Downingia concolor var. concolor	Downingia
Caryophyllaceae	
Cerastium arvense subsp. strictum	Meadow chickweed
**Silene gallica*	Windmill-pink
Convolvulaceae	
**Convolvulus arvensis*	Bindweed
Cuscuta sp.	Dodder
Crassulaceae	
Crassula aquatica	Water pygmy-weed
Fabaceae	
**Lotus corniculatus*	Birdfoot trefoil
Lupinus bicolor	Bicolored lupine
**Medicago polymorpha*	California burclover
Trifolium ciliolatum	Foothill clover
**Trifolium dubium*	Little hop clover
**Trifolium fragiferum*	Strawberry clover
**Trifolium hirtum*	Rose clover
**Trifolium incarnatum*	Crimson clover
**Trifolium repens*	White clover
**Trifolium subterraneum*	Subterranean clover
Trifolium variegatum	White-tip clover
**Vicia benghalensis*	Purple vetch
**Vicia sativa*	Common vetch
Gentianaceae	
Zeltnera muehlenbergii	June centaury
Geraniaceae	
**Erodium botrys*	Broad-leaf filaree
**Erodium cicutarium*	Red-stem filaree
**Erodium moschatum*	White-stem filaree
**Geranium dissectum*	Cut-leaf geranium
Gentianaceae	
Zeltnera muehlenbergii	June centaury

Table 1. Plant Species Observed on the Project Site[2]	
Family/Genius[3]/Species/Subspecies	**Common Name**
Lamiaceae	
**Mentha pulegium*	Pennyroyal
Stachys albens	White-stem hedge-nettle
Linaceae	
**Linum bienne*	Flax
Lythraceae	
**Lythrum hyssopifolia*	Hyssop loosestrife
Malvaceae	
**Malva parviflora*	Cheeseweed
Montiaceae	
Claytonia perfoliata	Miner's lettuce
Myrsinaceae	
**Lysimachia arvensis*	Scarlet pimpernel
Onagraceae	
Epilobium brachycarpum	Summer cottonweed
Epilobium ciliatum	Hairy willow-herb
Taraxia ovata	Sun cup
Orobanchaceae	
**Bellardia trixago*	Mediterranean linseed
Castilleja attenuate	Valley tassels
Castilleja exserta subsp. exserta	Purple owl's-clover
**Parentucellia viscosa*	Yellow glandweed
Triphysaria versicolor subsp. faucibarbata	Yellow owl's-clover
Plantaginaceae	
Callitriche marginate	Winged water starwort
**Plantago lanceolata*	English plantain
**Veronica anagallis-aquatica*	Water speedwell
Veronica peregrina subsp. Xalapensis	Purslane speedwell
Polygonaceae	
**Polygonum aviculare*	Common knotweed
**Rumex acetosella*	Sheep sorrel
**Rumex crispus*	Curly dock
**Rumex pulcher*	Fiddle dock
Ranunculaceae	
**Ranunculus muricatus*	Spiny-fruit buttercup
Ranunculus pusillus	Low buttercup
Rosaceae	
**Rubus armeniacus*	Himalayan blackberry
Rubiaceae	
Galium aparine	Goose grass

Table 1. Plant Species Observed on the Project Site[2]	
Family/Genius[3]/Species/Subspecies	**Common Name**
Verbenaceae	
Phyla nodiflora	Common frog fruit
MONOCOTS	
Alismataceae	
**Alisma lanceolatum*	Lance-leaf water-plantain
Cyperaceae	
Cyperus eragrostis	Tall flatsedge
Eleocharis macrostachya	Creeping spikerush
Schoenoplectus acutus var. occidentalis	Common tule
Iridaceae	
Sisyrinchium bellum	Western blue-eyed grass
Juncaceae	
Juncus balticus subsp. Ater	Baltic rush
Juncus bufonius var. bufonius	Toad rush
Juncus mexicanus	Mexican rush
Juncus phaeocephalus	Brown-headed rush
Juncus xiphioides	Iris-leaved rush
Juncaginaceae	
Triglochin scilloides	Flowering quillwort
Poaceae	
**Aegilops triuncialis*	Barbed goatgrass
**Avena barbata*	Slender wild oat
**Briza minor*	Small quaking grass
**Bromus diandrus*	Ripgut grass
**Bromus hordeaceus*	Soft chess
**Elymus caput-medusae*	Medusahead
Elymus multisetus	Big squirreltail
Elymus triticoides	Creeping wildrye
**Festuca bromoides*	Brome fescue
**Festuca perennis*	perennial ryegrass
**Holcus lanatus*	Common velvet grass
Hordeum brachyantherum	Meadow barley
**Hordeum marinum subsp. Gussoneanum*	Mediterranean barley
**Hordeum murinum subsp. leporinum*	Hare barley
**Phalaris aquatica*	Harding grass
**Phalaris paradoxa*	Paradox canary-grass
Pleuropogon californicus var. californicus	Annual semaphore grass
**Poa annua*	Annual bluegrass
**Polypogon interruptus*	Ditch beard grass
**Polypogon monspeliensis*	Annual beard grass

Table 1. Plant Species Observed on the Project Site[2]	
Family/Genius[3]/Species/Subspecies	**Common Name**
Themidaceae	
Brodiaea elegans subsp. elegans	Harvest brodiaea
Dichelostemma capitatum subsp. capitatum	Blue dicks
Triteleia laxa	Ithuriel's spear
Typhaceae	
Typha latifolia	Broad-leaved cattail

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
ANIMALS			
Invertebrates			
Valley Elderberry longhorn beetle (*Desmocerus californicus dimorphus*)	FT/--	Inhabits blue elderberry bushes (host plant); restricted to the Central Valley and adjacent foothills.	Not present. Suitable habitat is not present at the project site. No elderberry plants were observed during the field review.
Callippe silverspot butterfly (*Speyeria callippe callippe*)	FE/--	Habitat for this species is grassland, often with a significant component of native grasses including the host plant (*Viola pedunculata*) and characterized by shallow rocky soils and numerous rock outcrops.	Not present. Suitable habitat is not present at the site.
Monarch butterfly (*Danaus plexippus*) (wintering sites)	--/--	Winter roost sites located in wind-protected tree groves (eucalyptus, Monterey pine, cypress) with nectar and water sources nearby. Larval host plant is milkweed, primarily of the genus *Asclepias*.	Not present. Suitable habitat for an overwintering site is not present at the site. No milkweed plants of the genus *Asclepias* were found on the property.
California freshwater shrimp *(Syncaris pacifica)*	FE/CE	Found in low elevation, low gradient streams where riparian cover is moderate to heavy. Prefers shallow pools removed from the main flow. In winter, prefers undercut banks with exposed roots; in	Not present. Suitable habitat is not present at the site.

[4] Source: California Natural Diversity Data Base, Natural Heritage Division, California Department of Fish and Wildlife for the Cuttings Wharf 7.5 Minute Quadrangle Map and surrounding areas, February 2021.

[5] Definitions of status codes can be found in Table 4.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
		summer low flows, clings to submerged portions of overhanging tree shrub branches.	
Vernal pool fairy shrimp (*Branchinecta lynchi*)	FT/--	Inhabits vernal pools; occurs throughout the Delta and Central Valley.	Not present. Protocol surveys were negative for this species.
Western ridged mussel (*Gonidea angulata*)	--/--	Primarily creeks and rivers and less often lakes. Originally found in most of California, but now extirpated from Central and Southern California. Specimens known from Napa River area.	Not present. Suitable habitat is not present at the site.
Fish			
Steelhead – Central CA Coast ESU (*Oncorhynchus mykiss*)	FT/CSC	Well-oxygenated streams with riffles; loose, silt-free gravel substrate.	Not present. Suitable habitat is not present at the site.
Longfin smelt *(Spirinchus thaleichthys)*	FC/CE,CSC	Found in open waters of estuaries, mostly in the middle or bottom of the water column. Euryhaline, nektonic and anadromous. Prefers salinities of 15030 ppt but can be found in both freshwater and seawater.	Not present. Suitable habitat is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Delta smelt (*Hypomesus transpacificus*)	FT/CT	During spawning they migrate upstream into shallow fresh or slightly brackish tidally-influenced backwater sloughs and channel edges. In Solano County, Delta Smelt are found in Suisun Bay/Suisun Marsh sloughs upstream through the delta in Contra Costa, Sacramento, San Joaquin, Solano and Yolo counties.	Not present. Suitable habitat is not present at the site.
Sacramento splittail (*Pogonichthys macrolepidotus*)	--/CSC	Adult Sacramento Splittail migrate upstream from brackish areas to spawn in freshwater areas subject to flooding, such as the lower reaches of rivers, dead end sloughs, and in larger sloughs such as Montezuma Slough.	Not present. Suitable habitat is not present at the site.
Amphibians			
Foothill yellow-legged Frog (*Rana boylii*)	--/CSC	Partly-shaded, shallow streams and riffles with a rocky substrate in a variety of habitats. Need at least some cobble-sized substrate for egg-laying; larvae need at least 15 weeks to attain metamorphosis.	Not present. Suitable habitat is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
California red-legged frog *(Rana draytonii*)	FT/CSC	Mostly found in lowlands and foothills in/near permanent sources of deep water but will disperse far during and after rain. Prefers shorelines with extensive vegetation. Requires 11-20 weeks of permanent water for larval development and requires access to aestivation habitat.	Not present. Suitable habitat is not present at the site as verified by a protocol Phase 1 Habitat Assessment.
Reptiles			
Western pond turtle (*Emys marmorata*)	--/CSC	Aquatic turtle of ponds, marshes, rivers, streams, and irrigation ditches with aquatic vegetation. Needs basking sites and suitable upland habitat for egg-laying (sandy banks or grassy open fields).	Not present. Suitable habitat is not present at the site.
Birds			
Great blue heron (*Ardea herodias*) (Rookery)	--/--	Colonial nester in tall trees, cliff sides, and sequestered spots on marshes. Rookery sites in close proximity to foraging areas: marshes, lake margins, tide-flats, rivers and streams, wet meadows.	Not present. Suitable habitat for a rookery is not present at the site.
Black-crowned night-heron *(Nycticorax nycticorax)* [Nesting]	--/--	Colonial nester, usually in trees but occasionally in tule patches. Rookery sites are located adjacent to foraging areas including lake margins, mud-bordered bays and marshy spots.	Not present. Suitable habitat for nesting is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Golden eagle (*Aquila chrysaetos*) [nesting and wintering]	BCC/FP, WL	Typically frequents rolling foothills, mountain areas, sage-juniper flats and desert.	Not present as a nesting species. Suitable nesting habitat is not present at the site. Seen foraging on the property in spring 2021. Preconstruction nesting surveys are required to ensure no indirect impacts to eagles that could nest nearby.
Northern harrier (*Circus cyaneus*) [Nesting]	--/CSC	Coastal salt marsh and freshwater marsh; nests and forages in grasslands; nests on ground in shrubby vegetation, usually at marsh edge.	Possible. Suitable nesting habitat may be present at the site. Observed on site during winter as well as nesting season. Preconstruction nesting surveys are required to ensure no impact to nesting birds.
White-tailed kite (*Elanus caeruleus*) [nesting]	--/CFP	Open grassland and agricultural areas throughout Central California.	Not present. Suitable nesting habitat is not present on site. Species observed foraging on the site during winter.
Cooper's hawk (*Accipiter cooperii*) [nesting]	-/WL	Nests primarily in deciduous riparian forests; forages in open woodlands.	Not present. Suitable nesting habitat is not present on site. Species likely forages on or near the site, especially in winter.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Sharp-shinned hawk (*Accipiter striatus*) [nesting]	--/WL	Breeds in ponderosa pine, black oak, riparian deciduous, mixed conifer, and Jeffrey pine habitats. Prefers, but not restricted to, riparian habitats. All habitats except alpine, open prairie, and bare desert used in winter.	Not present. Suitable nesting habitat is not present on site. Species likely forages on or near the site, especially in winter.
Swainson's hawk (nesting) *(Buteo swainsoni)*	BCC/CT	Nests in trees and riparian stands; summer migrant to Central Valley. Suitable foraging areas include grasslands, pastures, alfalfa and other hay crops, and certain grain and row croplands.	Not present as a nesting species. Suitable nesting habitat is not present at the site. Seen foraging on the property in spring 2021. Preconstruction nesting surveys are required to ensure no indirect impacts to Swainson's hawks that could nest nearby.
Ferruginous hawk *(Buteo reglais)* (wintering)	--/WL	Inhabits open country. Winters in small numbers along California coast and inland valleys.	Wintering possible. The site is considered suitable winter foraging habitat, however, the species has not been observed using the site.
Osprey (*Pandion haliaetus*) [Nesting]	--/WL	Breeds in northern California from the Cascade Ranges south to Lake Tahoe, and along the coast south to Marin County. Associated strictly with large, fish-bearing waters, primarily in Ponderosa pine through mixed conifer habitats. Nests on Inverness Ridge.	Not present. Suitable nesting habitat is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
American Peregrine falcon (*Falco peregrinus anatum*)	BCC/FP	Nests in woodland, forest, and coastal habitats, on cliffs or banks, and usually near wetlands, lakes, rivers, sometimes on human-made structure. In non-breeding seasons found in riparian areas and coastal and inland wetlands.	Not present. Occurs in the area but suitable nesting habitat is not present at the site.
Merlin (*Falco columbarius*) [wintering]	-/WL	Breeds in Canada, winters in a variety of California habitats, including grasslands, savannahs, wetlands, etc.	Not present. May occasionally forage at the site during the winter.
Ridgway's (California clapper) rail (*Rallus obsoletus*)	FE/CE,FP	Found in saltwater marshes traversed by tidal sloughs in the vicinity of San Francisco Bay; associated with abundant growths of pickleweed; feeds on mollusks obtained from mud-bottomed sloughs.	Not present. Suitable habitat is not present at the site.
California black rail *(Laterallus jamaicensis coturniculus*)	--/CT,FP	Mainly inhabits salt-marshes bordering larger bays. Occurs in tidal salt marsh with dense growths of pickleweed; also occurs in freshwater and brackish marshes.	Not present. Suitable habitat is not present at the site.
Yellow rail (*Coturnicops noveboracensis*)	BCC/CSC	Found in freshwater marshes. Summer resident in the eastern Sierra and Modoc County.	Not present. Suitable habitat is not present at the site.
Western snowy plover (*Charadrius alexandrinus nivosus*) [nesting]	FT,BCC/CSC	Found on sandy beaches or marine and estuarine shores; also salt pond levees and shores of large alkali lakes; requires sandy, gravelly or friable soil substrate for nesting.	Not present. Suitable habitat is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Caspian tern *(Hydroprogne caspia)*	BCC/--	Nests on sandy or gravely beaches and shell banks in small colonies inland and along the Coast. Found in inland freshwater lakes and marshes, and also brackish or salt waters of estuaries and bays.	Not present. Suitable habitat is not present at the site.
Burrowing owl (*Athene cunicularia*)	BCC/CSC	Found in open dry annual or perennial grasslands, deserts and scrublands characterized by low growing vegetation. This species is a subterranean nester, dependent upon burrowing mammals, most notably the California ground squirrel.	Not present. Suitable habitat is not currently present at the site due to general lack of ground squirrels and ground squirrel colonies. Could possibly inhabit the site in the future. Preconstruction nesting surveys are required to ensure no impact to nesting birds.
Short-eared owl (*Asio flammeus)* (nesting)	--/CSC	Found in marshes, both freshwater and salt; lowland meadows; irrigated alfalfa fields. Tule patches/full grass needed for nesting and daytime seclusion. Nests on dry ground in a depression concealed in vegetation.	Not present. Suitable habitat is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Bank swallow *(Riparia riparia)* (nesting)	--/CT	A migrant found primarily in riparian and other lowland habitats in California west of the deserts. A spring and fall migrant in the interior, less common on coast; an uncommon and very local summer resident. In summer, restricted to riparian areas with vertical cliffs and banks with fine-textured or sandy soil, into which it digs its nesting holes.	Not present. Suitable habitat is not present at the site.
Loggerhead shrike (*Lanius ludovicianus*)	BCC/CSC	Habitat includes open areas such as desert, grasslands and savannah. Nests in thickly foliaged trees or tall shrubs. Forages in open habitats, which contain trees, fence posts, utility poles, and other perches.	Not present. Suitable habitat is not present at the site.
San Francisco common yellowthroat (*Geothlypis trichas sinuosa*)	BCC/CSC	Requires thick continuous cover down to water surface for foraging; tall grasses, tule patches, willows for nesting.	Not present. Suitable habitat is not present at the site.
Yellow warbler *(Dendroica petechia*) [nesting]	BCC/CSC	Breeds in deciduous riparian woodlands, widespread during fall migration.	Not present. Suitable habitat is not present at the site.
San Pablo song sparrow *(Melospiza melodia samuelis)*	BCC/CSC	Tidal, brackish or salt marshes, San Pablo Bay.	Not present. Suitable habitat is not present at the site.
Suisun song sparrow *(Melospiza melodia maxillaris)*	BCC/CSC	Forages and nests in dense marsh and scrub habitat along the margins of Suisun Bay.	Not present. Suitable habitat is not present at the site.

TABLE 2. SPECIAL STATUS ANIMAL SPECIES THAT HAVE BEEN REPORTED IN THE VICINITY OF THE PROJECT SITE, CITY OF AMERICAN CANYON, CALIFORNIA[4]			
SPECIES	**STATUS CODES[5] FED/STATE**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Tri-colored blackbird (*Agelaius tricolor*) [Nesting colony]	BCC/CE,CSC	Breeds near freshwater, usually in tall emergent vegetation. Requires open water with protected nesting substrate. Colonies prefer heavy growth of cattails and tules. Uses grasslands and agricultural lands for foraging.	Not present. Suitable habitat is not present at the site.
Mammals			
Salt Marsh harvest mouse (*Reithrodontomys raviventris*)	FE/CE,FP	Inhabits saline emergent wetlands in the San Francisco Bay and its tributaries. Pickleweed is the primary habitat.	Not present. Suitable habitat is not present at the site.
Suisun shrew *(Sorex ornatus sinuosus)*	--/CSC	Inhabits tidal marshes along the northern shores of San Pablo and Suisun Bays.	Not present. Suitable habitat is not present at the site.
American badger (*Taxidea taxus*)	--/CSC	Drier open stages of most shrub, forest, and herbaceous habitats; needs sufficient food, friable soils and open, uncultivated ground.	Not present. Suitable habitat is not present at the site.
Pallid bat *Antrozous pallidus*	--/CSC	Roosts primarily in oak woodland and ponderosa pine habitats; forages in open areas.	Not present. Suitable habitat is not present at the site.

TABLE 3. SPECIAL STATUS PLANTS WITH POTENTIAL TO OCCUR IN THE VICINITY OF THE PROJECT SITE, AMERICAN CANYON, CALIFORNIA[6]			
SPECIES	**STATUS CODES[7] FED/STATE/CNPS**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Henderson's bent grass *(Agrostis hendersonii)*	--/--/3.2	Found in moist places in valley and foothill grassland or vernal pools. 65-1030m.	Not present. Suitable habitat is not present at the site.
Franciscan onion (*Allium peninsulare franciscanum*)	--/--/1B.2	Found in cismontane woodland and valley and foothill grassland in clay soils and serpentine on dry hillsides. 100-300m.	Not present. Suitable habitat is not present at the site.
Napa false indigo (*Amorpha californica* var. *napensis*)	--/--/1B.2	Broadleafed upland forest, chaparral, cismontane woodland. Openings in forest or woodland or in chaparral. 150-2000m.	Not present. Suitable habitat is not present at the site.
Alkali Milk-vetch (*Astragalus tener* var. *tener*)	--/--/1B.2	Inhabits low ground, alkali flats and flooded land in valley and foothill grasslands or in playas or vernal pools. 1-170m.	Not present. Suitable habitat is not present at the site.
Big-scale (California) balsamroot (*Balsamorhiza macrolepis var. macrolepis*)	--/--/1B.2	Chaparral, cismontane woodland, valley and foothill grassland, sometimes on serpentinite. 90-1555m.	Not present. Suitable habitat is not present at the site.
Big tarplant (*Blepharizonia plumosa*)	--/--/1B.1	Valley and foothill grasslands. Found in dry hill and plains in annual grassland in clay and clay-loam soils, usually on slopes. Often in burned areas. 60-505m.	Not present. Suitable habitat is not present at the site.
Narrow-anthered brodiaea (*Brodiaea leptandra*)	--/--/1B.2	Broadleafed upland forest, chaparral, lower montane coniferous forest. 110-915m. Nearest location is near Mt. George about 4 miles northeast of the site.	Not present. Suitable habitat is not present at the site.

TABLE 3. SPECIAL STATUS PLANTS WITH POTENTIAL TO OCCUR IN THE VICINITY OF THE PROJECT SITE, AMERICAN CANYON, CALIFORNIA[6]			
SPECIES	**STATUS CODES[7] FED/STATE/CNPS**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Lyngbye's sedge (*Carex lyngbyei*)	-/-/2B.2	Marshes and swamps (brackish or freshwater) at sea level.	Not present. Suitable habitat is not present at the site.
Tiburon paintbrush (*Castilleja affinis* ssp. *neglecta*)	FE/ST/1B.2	Rocky serpentine sites within valley and foothill grassland. 75-400m.	Not present. Suitable habitat is not present at the site.
Rincon Ridge ceanothus (*Ceanothus confuses)*	--/--/1B.1	Known from volcanic or serpentine soils on dry shrubby slopes in closed-cone coniferous forest, chaparral, and cismontane woodland. 75-1065m.	Not present. Suitable habitat is not present at the site.
Holly-leaved ceanothus (*Ceanothus purpureus)*	--/--/1B.2	Rocky volcanic slopes in chaparral. 120-640m.	Not present. Suitable habitat is not present at the site.
Congdon's tarplant (*Centromedia parryi congdonii*)	--/--/1B.2	Alkaline soils in valley and foothills grassland.	Not present. Suitable habitat is not present at the site.
Pappose tarplant (*Centromadia parryi ssp. parryi*)	--/--/1B.2	Found in mesic and often alkaline site in coastal prairie, meadows and seeps, coastal salt marsh and valley and foothill grasslands. 2-420m	Not present. Suitable habitat is not present at the site.
Soft salty bird's beak *Chloropyron molle ssp. molle*	FT/--/1B.1	Found in Coastal salt marsh with *Distichlis*, *Salicornia, Frankenia*, etc. 0-5 m.	Not present. Suitable habitat is not present at the site.
Bolander's water-hemlock (*Cicuta maculata* var. *bolanderi*)	--/--/2B.1	Fresh or brackish water marshes. 0-200m.	Not present. Suitable habitat is not present at the site.
Dwarf Downingia (*Downingia pusilla*)	--/--/2B.2	Inhabits vernal pools and vernal lake margins. 1-445m.	Not present. Suitable habitat is not present at the site.
Greene's narrow-leaved daisy (*Erigeron greenei*)	--/--/1B.2	Serpentine and volcanic substrates in chaparral. 75-1060m.	Not present. Suitable habitat is not present at the site.
Jepson's coyote-thistle *(Eryngium jepsonii)*	--/--/1B.2	On clay soils in vernal pools and valley and foothill grassland. 3-305 m.	Not present. Suitable habitat is not present at the site.

TABLE 3. SPECIAL STATUS PLANTS WITH POTENTIAL TO OCCUR IN THE VICINITY OF THE PROJECT SITE, AMERICAN CANYON, CALIFORNIA[6]			
SPECIES	**STATUS CODES[7] FED/STATE/CNPS**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
San Joaquin spearscale (*Etriplex joaquiniana*)	--/--/1B.2	Chenopod scrub, meadows, playas, valley and foothill grassland and vernal pools. Usually in seasonal alkali wetlands or alkali sink scrub with *Distichlis*, *Frankenia*, etc. 1-835m.	Not present. Suitable habitat is not present at the site.
Fragrant fritillary (*Fritillaria liliacea*)	--/--/1B.2	Coastal scrub, valley and foothill grassland, coastal prairie. Often on serpentine; various soils reported though usually clay, in grassland. 3-410m.	Not present. Suitable habitat is not present at the site.
Diablo helianthela *(Helianthela castenea)*	--/--/1B.2	Broadleaved upland forest, chaparral, cismontane woodland, coastal scrub, riparian woodland, valley and foothill grassland. Usually in chaparral/oak woodland interface in rocky, azonal soils. Often in partial shade. 25-1150m.	Not present. Suitable habitat is not present at the site.
Brewer's western flax (*Hesperolinon breweri*)	--/--/1B.2	Chaparral, cismontane woodland and valley and foothill grassland; often found in rocky serpentine soil in serpentine chaparral and serpentine grassland. 30-885 m.	Not present. Suitable habitat is not present at the site.
Carquinez goldenbush *(Isocoma argute)*	--/--/1B.1	Found in Valley and Foothill grassland. On alkaline soils, flats and lower hill. Found on low benches near drainages and on tops and sides of mounds in swale habitat. 1-50 m.	Not present. Suitable habitat is not present at the site.

TABLE 3. SPECIAL STATUS PLANTS WITH POTENTIAL TO OCCUR IN THE VICINITY OF THE PROJECT SITE, AMERICAN CANYON, CALIFORNIA[6]			
SPECIES	**STATUS CODES[7] FED/STATE/CNPS**	**HABITAT**	**OCCURRENCE ON THE PROJECT SITE**
Contra Costa goldfields (*Lasthenia conjugens*)	FE/--/1B.1	Vernal pools, swales, low depressions, in open grassy areas. 1-445m. Extirpated from most of its range. Most remaining occurrences restricted to the Fairfield region.	Not present. Suitable habitat is not present at the site.
Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*)	--/--/1B.2	Inhabits the banks of sloughs and bays in the Suisun Bay and Delta. Found in freshwater and brackish marshes.	Not present. Suitable habitat is not present at the site.
Legenere (*Legenere limosa*)	--/--/1B.1	Inhabits the beds of vernal pools. 1-880m.	Not present. Suitable habitat is not present at the site.
Jepson's leptosiphon (*Leptosiphon jepsonii*)	--/--/1B.2	Found on volcanics or the periphery of serpentine substrates in chaparral, cismontane woodland, and open to partially shaded grassy slopes. 55-855 m.	Not present. Suitable habitat is not present at the site.
Mason's lilaeopsis (*Lilaeopsis masonii*)	--/Rare/1B.1	Freshwater and brackish marshes, riparian scrub. Tidal zones, in muddy or silty soil formed through river deposition or river bank erosion. 0-10m.	Not present. Suitable habitat is not present at the site.
Marin knotweed (*Polygonum marinense*)	--/--/3.1	Coastal salt marshes and brackish marshes. 0-10m.	Not present. Suitable habitat is not present at the site.
California beaked-rush (*Rhynchospora californica*)	--/--/1B.1	Freshwater seeps and open marshy areas in bogs, fens, marshes and swamps and lower montane coniferous forest. 45-1000m.	Not present. Suitable habitat is not present at the site.
Chaparral ragwort *(Senecio aphanactis)*	--/--/1B.2	Known from foothill woodland and chaparral habitats.	Not present. Suitable habitat is not present at the site.
Napa checkerbloom *(Sidalcea hickmanii* ssp. *napensis)*	--/--/1B.1	Occurs on rhyolite substrates in chaparral. 415-610m.	Not present. Suitable habitat is not present at the site.

SUMMARY

This report is a Habitat Assessment for the federally threatened California red-legged frog (*Rana draytonii*, hereafter CRLF) at the location of the approximately 210-acre infill development [=Giovannoni Logistics Project] between Devlin Road to the north and Green Island Road to the south in the northwestern part of the City of American Canyon, Napa County (Project). The Project is now nearly entirely surrounded by industrial businesses and warehouse buildings, along with other structures, as well as Southern Pacific Railroad tracks to the south and east, and Highway 29 to the east. The Napa River estuary lies further to the west.

The Project site consists of an open field with a mosaic non-native annual grasses and seasonal wetlands. It is subject to sheet flooding which eventually drains northwest into an unnamed channel which continues off-site under Devlin Road. There are no connections with other stream courses which drain the agricultural fields and hills east of Highway 29. The area is relatively flat with an elevational range of approximately 20-50 feet.

The closest known CRLF records to the site are 0.6-2.4 miles to the east and southeast; additional CRLF records 3.7 miles and further away lie within Critical Habitat designated for this species (SOL-2 and SOL-3). All of these records lie east of Highway 29 which is a major barrier to any potential movements of CRLF to the west due to continuous traffic, highway berms, and the re-routing of drainages into culverts under the freeway. Additionally, the Project is completely isolated from all areas to the east by Highway 29, railroads, buildings, and other urban infrastructure, and there are no hydrologic connections with any stream channels off-site to the east of Highway 29. Finally, there is no suitable breeding or rearing habitat for CRLF on site due to the shallow and ephemeral nature of the seasonal wetlands and the lack of any suitable riparian vegetation for cover. Thus, it is my professional opinion that the Project site lacks habitat for this species and that CRLF cannot access the site from surrounding occupied habitats to the east and southeast.

1.0 INTRODUCTION

A proposed development for 6 warehouse and office buildings on the Giovannoni Parcel within the northwest portion of the City of American Canyon, Napa County, California, has been proposed (Figure 1). Since the 210-acre site lies within the historic range for the California red-legged frog (*Rana draytonii*, hereafter CRLF) [Stebbins 2003], and is near occupied Critical Habitat for CRLF (USFWS 2010), a habitat assessment was conducted for this species.

2.0 PROJECT DESCRIPTION AND SETTING

The 210-acre project site is located between Devlin Road to the north and Green Island Road to the south in the northwestern part of American Canyon, Napa County (Project) [Figure 1]. The Project is now nearly entirely surrounded by industrial businesses and warehouse buildings,

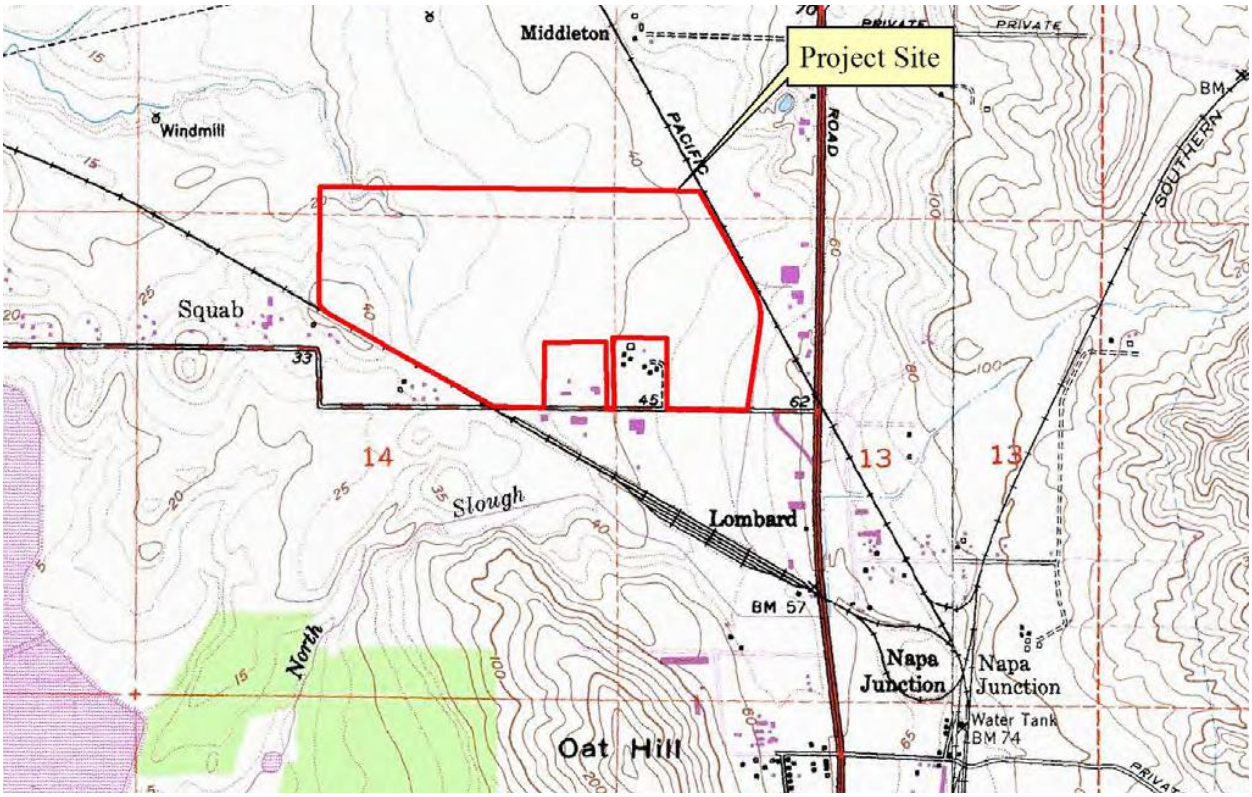

Figure 1. Location of 210-acre Giovannoni parcel within the City of American Canyon.

along with other structures, as well as Southern Pacific Railroad tracks to the south and east, and Highway 29 to the east (Figure 2). The Napa River estuary lies further to the west.

Figure 2. Location of the 210-acre Giovannoni parcel in American Canyon showing surrounding infrastructure and development. Google Earth photograph taken in 2020.

The Project site consists of an open field with a mosaic non-native annual grasses and seasonal wetlands that has used for cattle (*Bos taurus*) grazing. It is subject to sheet flooding which eventually drains northwest into an unnamed channel which continues off-site under Devlin Road and eventually drains into the Napa River estuary. There are no connections with other stream courses which drain the agricultural fields and hills east of Highway 29. The area is relatively flat with an elevational range of approximately 20-50 feet.

The Project site has been previously surveyed and mapped for wetlands by Monk and Associates (2018). They also conducted surveys for special status plants and animals, including CRLF on a small portion of the site (for the Devlin Road and Napa Valley Vine Trail Project). All of the wetlands were determined to be shallow and seasonal, with inundation limited to only about 3-4 months during the year after sufficient winter and spring rainfall.

There are no trees or dense riparian vegetation thickets of any type on site. Botta pocket gopher (*Thomomys bottae*) and California vole (*Microtus californicus*) burrows are scattered throughout the more upland areas.

3.0 METHODS

The methods employed to produce this report include evaluating the suitability of habitat for CRLF on site by conducting a reconnaissance-level site visit during the day by me on 10 February 2021. I followed the U.S. Fish and Wildlife Service protocol for the CRLF habitat assessment (USFWS 2005) and made observations regarding any amphibians and reptiles observed, or potentially inhabiting the vicinity. Additionally, CRLF occurrence records within 3.1 miles of the Project site (CNDDB 2021) were mapped. Finally, I examined 7.5' USGS quadrangles and aerial photographs for potentially suitable aquatic habitats within a 3.1-mile radius of the site and connectivity of these habitats with the Project site.

4.0 RESULTS AND DISCUSSION

No CRLF were observed during my day visit of the Project site on February 10, 2021 (see Appendix). I also did not observe any other amphibian species other than some Pacific treefrog (*Hyla regilla*) egg masses.

Suitable breeding and rearing habitat for CRLF is generally characterized by dense, shrubby riparian vegetation associated with deep (>2.3 feet), still or slow-moving water (see Jennings and Hayes 1994, Jennings 1988, Hayes and Jennings 1988). All of the inundated wetlands that I observed on site were too shallow and ephemeral to support a breeding population of CRLF.

These findings are consistent with previous findings recorded by Monk and Associates (2018) for a small portion of the proposed road alignments on through the eastern part of the Project site.

A review of the most recent California Natural Diversity Database files (CNDDB 2021) revealed that there are no records of CRLF in American Canyon west of Highway 29 almost certainly due to the high amount of vehicle traffic, highway berms, and stream courses being diverted into buried culverts below the freeway. Based on the data from the CNDDB, 3 CRLF occurrences are located within a 3.1-mile radius of the southeast corner of the Study Area, all located east of Highway 29 (Figure 3). The closest sighting is a single adult observed 0.6 miles to the east in the North Slough drainage on July 26, 2006, 2008 (Record #1062). The next closest is another single adult observed 1.1 miles to the southeast in a marsh area near an old quarry pond on August 04, 2008 (Record #896). The third closest is 2.4 miles to the southeast near the Flosden Road where multiple larvae, juveniles, and adults have been observed between 2008 and 2015 (Record #228). There are other records further away within Critical Habitat units SOL-2 and SOL-3 to east and southeast. However, there are no hydrologic connections with any streams that drain the agricultural fields and adjacent foothills east of Highway 29 (a finding also noted by Monk and Associates (2018, 2019). Additionally, the Project site is now nearly entirely surrounded by extensive urban development and infrastructure. Thus, there is no chance for any CRLF to access the site from occupied habitats to the east and southeast due to the presence of Highway 29 (as described above), as well as railroads, urban streets, fences, and buildings.

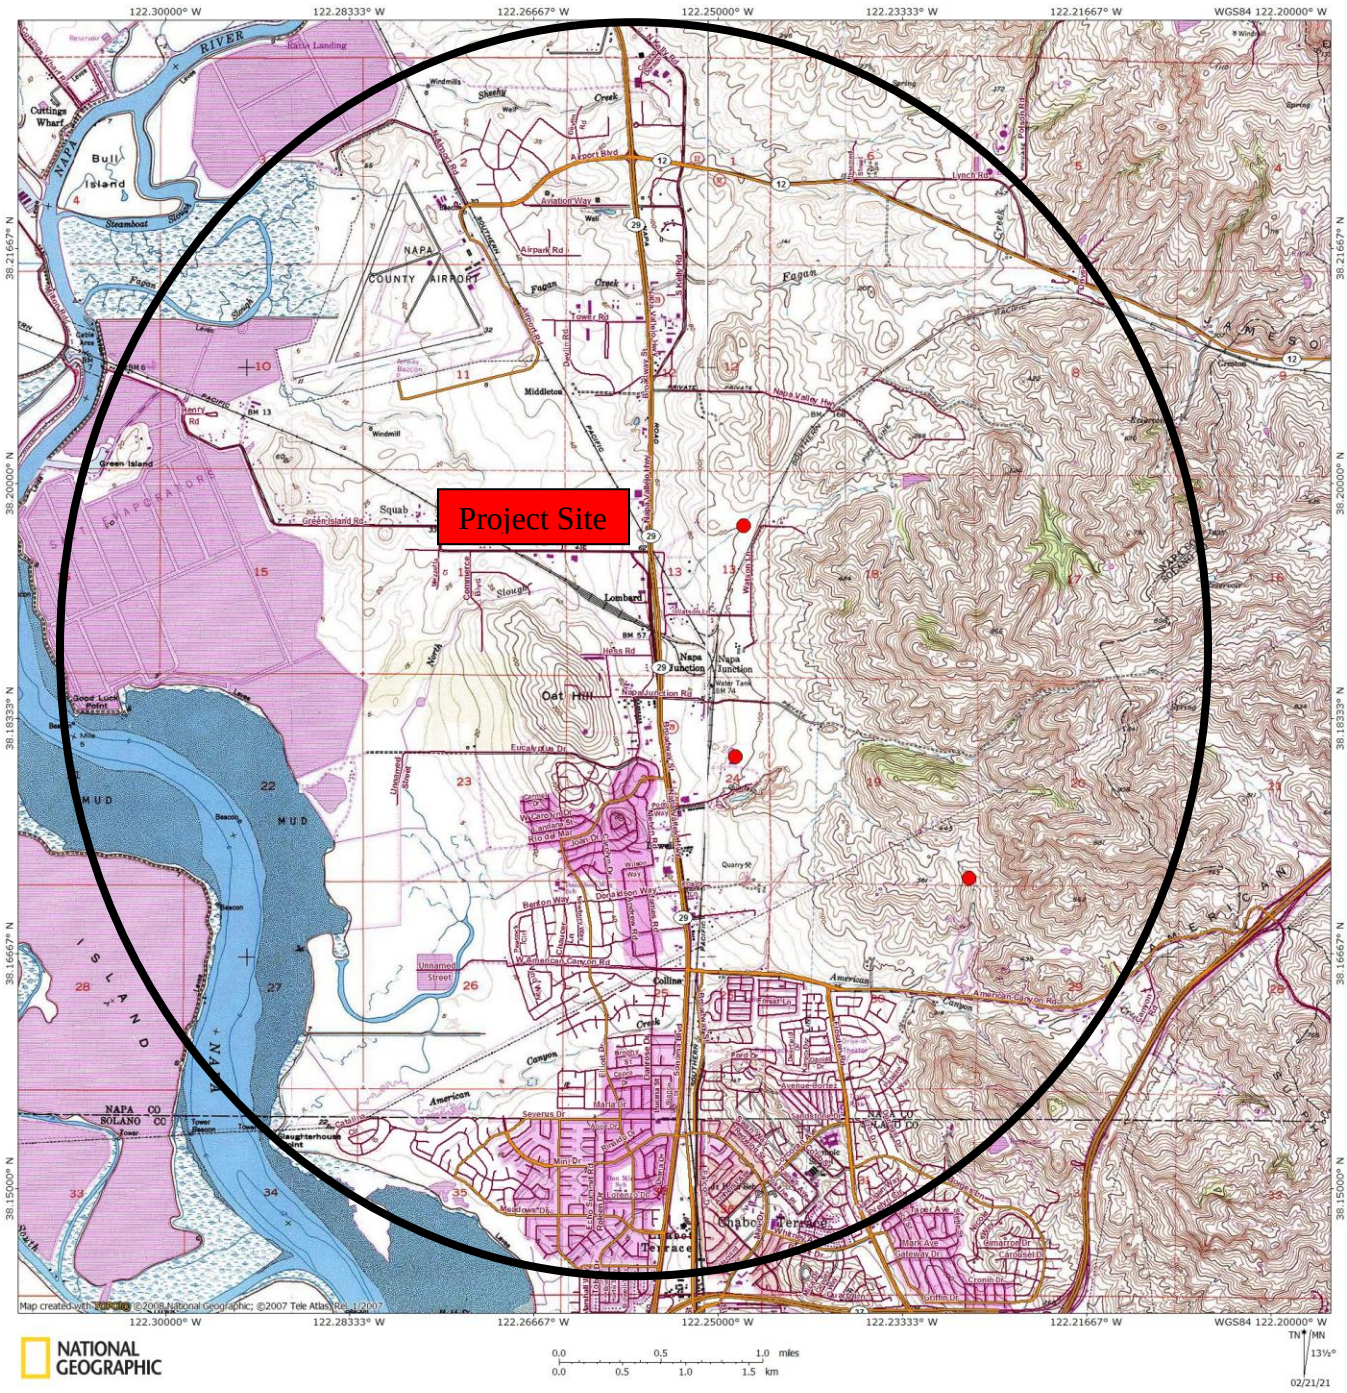

Figure 3. Locations of CRLF within 3.1 miles of the southeast corner of the Project site.

5.0 CONCLUSIONS

Although occupied CRLF habitat is present within 0.6-2.4 miles east and southeast of the Project site, all of these records lie east of Highway 29 which is a major barrier to any potential movements of CRLF to the west due to continuous traffic, highway berms, and the re-routing of

drainages into culverts under the freeway. Additionally, the Project is completely isolated from all areas to the east by Highway 29, railroads, buildings, and other urban infrastructure, and there are no hydrologic connections with any stream channels off-site to the east of Highway 29.. Finally, there is no suitable breeding or rearing habitat for CRLF on site due to the shallow and ephemeral nature of the seasonal wetlands and the lack of any suitable riparian vegetation for cover. Thus, it is my professional opinion that the Project site lacks habitat for this species and that CRLF cannot access the site from surrounding occupied habitats to the east and southeast.

Site Location: Napa, City of American Canyon, T.4N, R.4W, Sections 1(NE) and 13(NW
(County, General location name, UTM Coordinates or Lat./Long. or T-R-S)

****ATTACH A MAP** (include habitat types, important features, and species locations)**

Proposed project name: Giovannoni Logistics Project
Brief description of proposed action: Proposed development of 6 warehouse and office buildings on a 210-acre site in the northwest portion of the City of American Canyon

1) Is this site within the current or historic range of the CRF (circle one)? (YES) NO

2) Are there known records of CRF within 1.6 km (1 mi) of the site (circle one)? (YES) NO
If yes, attach a list of all known CRF records with a map showing all locations.

GENERAL AQUATIC HABITAT CHARACTERIZATION

(if multiple ponds or streams are within the proposed action area, fill out one data sheet for each)

POND:
Size: 8' x 15' Maximum depth: 4 inches

Vegetation: emergent, overhanging, dominant species: mostly sedges and grasses with a few cockleburs. No trees or denser riparian vegetation present

Substrate: clay and sand.

Perennial or Ephemeral (*circle one*). If ephemeral, date it goes dry: April - May most years

California Red-Legged Frog Habitat Site Assessment Data Sheet

STREAM:

Bank full width: 2 feet
Depth at bank full: 1 foot
Stream gradient: 2 degrees

Are there pools (circle one)? YES (NO)

If yes,

Size of stream pools: _____
Maximum Depth of stream Pools: _____

Characterize non-pool habitat: run, riffle, glide, other: Mostly riffle.

Vegetation: emergent, overhanging, dominant species: Grasses and sedges. No willows or cattails or tules.

Substrate: Clay and sand

Bank description: Ruderal grasslands.

Perennial or (Ephemeral) (*circle one*). If ephemeral, date it goes dry: April - May most years

Other aquatic habitat characteristics, species observations, drawings, or comments:

Only observed a Pacific treefrog egg masses. Lots of California vole and Botta pocket gopher burrows present.

Area used for livestock grazing. Now completely surrounded by development and urban infrastructure.

Wetlands too ephemeral and shallow to be used by CRLF. Thus, no habitat present. Also, no riparian connection with drainages to the east of Hwy 29. Therefore, adjacent CRLF occupied habitats to the east and southeast are disconnected from the project site and no overland movements can occur to the site.

Necessary Attachments:

1. All field notes and other supporting documents
2. Site photographs.
3. Maps with important habitat features and species locations

Geotechnical Engineering Report
GREEN ISLAND ROAD LOGISTICS CENTER
Green Island Road
American Canyon, California
WKA No. 12883.01
November 10, 2020

INTRODUCTION

As authorized, we have completed a geotechnical engineering study for the proposed Green Island Road Logistics Center to be constructed north of Green Island Road in American Canyon, California (see Figure 1). The purposes of this study have been to explore the existing site, soil, and groundwater conditions across the site, and to provide geotechnical engineering conclusions and recommendations for use by the other members of the design team in design and construction of the proposed industrial development. This report presents the results of our study.

Scope of Services

Our scope of services for this project has included the following tasks:

1. Site reconnaissance;
2. Review of previous geotechnical studies that included the project site and for a property within the near vicinity of the site;
3. Review of United States Geological Survey (USGS) topographic maps, historical aerial photographs and available groundwater information;
4. Subsurface explorations, including the drilling and sampling of 52 borings to depths ranging from approximately 10 to 31½ feet below the existing site grades;
5. Collection of representative bulk samples of near-surface soils;
6. Laboratory testing of selected soil samples;
7. Engineering analyses; and,
8. Preparation this report.

Figures and Attachments

This report contains a Vicinity Map as Figure 1; a Site Plan showing the approximate boring exploration locations as Figure 2; and, Logs of Soil Borings as Figures 3 through 54. An explanation of the symbols and classification system used on the logs is included as Figure 55. Appendix A contains general information regarding project concepts, exploratory methods used

during our field investigation, and laboratory test results not included on the boring logs. Appendix B contains *Guide Earthwork Specifications* that may be used in preparation of contract documents.

Proposed Development

Based on conversations with Mr. Joe Lavaich of Buzz Oats; review of *Preliminary Concept Site Plan* prepared by RMW Architecture Interiors dated August 8, 2020, we understand the proposed logistics center will include the construction of six warehouse/office buildings identified as Buildings A through F. The warehouse/office structures will encompass building footprints ranging from about 188,300 square feet (sf) up to 715,500 sf. We anticipate that the structures will be constructed of concrete tilt-up panels with interior concrete slabs-on-grade floors. Below grade basements are not anticipated. Structural loads for the buildings are anticipated to be heavy on the order of 150 kips for interior column loads and about 5 kips per lineal foot for exterior walls. Associated improvements will include the construction of underground utilities, landscaping, exterior flatwork, below-grade loading docks, retaining walls, asphalt pavements, and two storm water retention ponds. We anticipate that the storm water retention ponds will be about 5 to 10 feet in depth with unlined side slope gradients of three horizontal to one vertical (3H:1V) or flatter.

Grading plans were not available; however based on the existing site topography, we anticipate maximum excavations and fills on the order of one to five feet for development of the logistics center.

Supplemental Information

Supplemental information used in the preparation of this report included review of the following reports prepared by others and Wallace-Kuhl and Associates (WKA) for studies that included the site and for properties near the project site:

- Cornerstone Earth Group, 2017, *Geologic Fault Investigation New Sanitary Sewer Main* prepared for the Giovanni Property which is located within the site, Project No. 582-4-1;
- Wallace-Kuhl & Associates, Inc., 1994, *Geotechnical Engineering Report* prepared for Lot 5 of the Green Island Industrial Park, WKA No. 2652.02, March 1994;
- Wallace-Kuhl & Associates, Inc., 1994, *Geotechnical Engineering Report* prepared for the Graton Beverage Facility located on Lot 15 of the Green Island Industrial Park, WKA No. 2651.01, April 1994;

- Wallace-Kuhl & Associates, Inc., 1995, *Geotechnical Engineering Report* prepared for Spec Buildings 59 and 188 of the Green Island Industrial Park, WKA No. 2651.04, May 1995;

- Wallace-Kuhl & Associates, Inc., 2008, *Geotechnical Engineering Report* prepared for the Biagi Brothers Wine Distribution Center located adjacent to the west of the subject property, WKA No. 8005.01, March 2008.

FINDINGS

Site Description

The project site is located north of Green Island Road and about a quarter mile west of Highway 29 in American Canyon, California and encompasses a total area of approximately 208-acres. The site occupies land identified as Napa County Assessor Parcel Numbers 057-130-034, -036, and -038. The site is bounded to the north by commercial and industrial developments, beyond which is the Napa County Airport; to the east by Union Pacific Railroad lines, beyond which is commercial and industrial developments; to the south by commercial and industrial developments, Green Island Road, and Union Pacific Railroad lines; and, to the east by commercial and industrial developments.

The topography of the site is sloping gently from southeast to northwest. The highest portion of the site, the farthest southeast area, has a maximum surface elevation of about +55 feet msl and the lowest portion of the site, the farthest northwest area, has a surface elevation of about +25 feet msl, based on topographic information shown on the *USGS 7.5-Minute Topographic Map of the Cuttings Wharf Quadrangle, California*, dated 2018.

A drainage swale, dry at the time of our explorations, runs from north to south within the western portion of the site, a portion of this drainage swale is diverted through a large diameter pipe that is covered by soil to allow vehicle access between the two sides of the swale. The swale is approximately two feet deep.

At the time of our field explorations, performed between September 21, 2020, and October 2, 2020, the site was vacant pasture land covered with grassy low-lying vegetation.

Historical Aerial Photographic Review

We reviewed historical aerial photographs of the site available from our files and the Google Earth software. Available photographs were taken in the years 1948, 1958, 1968, 1982, 1993 and 2002 through 2020.

Review of the photographs taken from 1948 through 2020 show the site was an agricultural fallow area used for livestock grazing. A seasonal creek located in the northwest portion of the site trends in a northwest-west direction. There are three east-west trending smaller tributaries to the creek along the northern property line and about 200 and 350 feet south of the northern property line, and a north-south trending tributary approximately 1400 feet east of the western property line. Seasonal wetland depressions are observed throughout the site throughout each year. The locations of observed wetlands, are shown on the Site Plan, Figure 2.

General Site Geology

The site is located in the southern portion of Napa Valley which is characterized as a relatively large north-west tending alluvial valley located within the Northern California Coast Range geomorphic province. Various authors have mapped the local geology of the site area. These maps differ in scale and detail but agree that a majority site as being underlain by the late Pleistocene to Holocene age alluvial fan deposits (Qf) [Bezore, et al., 2002], which are bound to the north and west by older geologic units including Late Pleistocene fan deposits (Qpf) and early to middle Pleistocene alluvial fan and terrace deposits (Qoa). The Qf unit is relatively younger than and was deposited over the Qpf and Qoa units. The Qf unit is described as gently sloping, fan-shaped alluvial surfaces. Sediments include sand, gravel, silt and clays that are moderately to poorly sorted and moderately to poorly bedded. The Qpf unit is described as

gently sloping, fan-shaped alluvial surfaces where late Pleistocene age is indicated by slight dissection and/or the development of alfisols. The Qoa unit is described as moderately to deeply dissected alluvial deposits capped by alfisols, ultisols, or soils containing a silica or calcic hardpan.

The western portion of the site is mapped as Huichica Formation (QTh), part of the Sonoma Assemblage, of early Pleistocene and Pliocene age. The formations is described as fluvial gravel, sand, silt and clay.

Subsurface Soil Conditions

A total of 52 borings (D1 – D52) were performed at the site between September 21, 2020, and October 2, 2020. The approximate locations of the explorations are shown on the Site Plan, Figure 2. We also collected bulk samples of surficial soils at three locations within proposed pavement areas (B1 – B3).

The borings reveal the surface and near-surface soil conditions at the site consist of moderate to high plastic, stiff to hard, lean clay to depths about five to 10 feet below the existing ground surface (bgs). Underlying the upper clay soil were interbedded silty lean clays, sandy lean clays, clayey sands and silty sands to the maximum depth explored of 51½ feet bgs. The surface and near-surface soils across the site were observed to be relatively loose with frequent desiccation cracks to depths of about 6 to 18 inches.

The soil conditions encountered in the explorations for this study are consistent with soil conditions encountered in previous studies referenced in this report. For specific information regarding the soil conditions at a specific exploration location, please refer to the Logs of Soil Borings, Figures 3 through 54.

Groundwater

Groundwater was encountered in six of the 52 borings performed during our field work, at depths ranging from approximately 12 to 20 feet bsg. The borings were backfilled with neat-cement grout as required by the Napa County upon completion of the subsurface exploration program. Please note that the borings may not have been left open long enough for groundwater to reach static equilibrium.

To supplement the groundwater data obtained from the borings, we reviewed available groundwater information at the California Department of Water Resources (DWR) website. The DWR periodically monitors groundwater levels in wells across the state. Their website shows one well located near the sites border with the commercial and industrial development near the

middle of the site. The well is identified as Well No. 04N04W13E001M with ground surface elevations of about +44 feet msl, which is similar to the elevation at the project site. Groundwater data for this well was recorded from March 25, 1930 to at least April 18, 1962. Data shows the highest recorded groundwater depth at the well was about +33.5 feet msl (about 10.5 feet below the ground surface) at the well on March 28, 1952. The lowest recorded groundwater elevation was about +21.4 feet msl at the well (about 22.6 feet below the ground surface) at the well on September 6, 1961.

These groundwater conditions are consistent with the groundwater levels observed during the field explorations performed for this study. Similar groundwater can be expected during the proposed construction.

CONCLUSIONS

Fault Rupture

According to mapping by the California Geologic Survey, the western portion of the project site lies within a mapped Earthquake Fault Zone and Seismic Hazard Zone. In 2017, a geologic fault investigation was performed by the Cornerstone Earth Group to locate the potential surface trace of the West Napa Fault as part of a proposed sewer main alignment project. The investigation included a review of previously completed investigations performed by other consultants to locate and/or "clear" sites of fault surface traces, drilling an array of borings, and excavating three observation trenches along the suspected fault alignment. The West Napa Fault was confirmed as trending through the western portion of the project site. The approximate fault trace is shown on the Site Plan, Figure 2.

Further evaluation for the presence or absence of the West Napa Fault or the potential for fault rupture is beyond our scope of services for this project. The referenced Cornerstone Earth Group report should be submitted to the local building official to satisfy the requirements of the Alquist Priolo Fault Hazard Zone Act, if required.

Soil Expansion Potential

Laboratory testing of three representative near-surface clay soil samples collected from the proposed building footprint revealed these soils possess moderate to high plasticity when tested in accordance with the American Society of Testing and Materials (ASTM) D4318 test method (see Figures A1 through A4). Laboratory test results of the five near-surface clay soil samples also revealed these soils possess Expansion Indices ranging from 33 to 108, equivalent to a "*low to high*" expansion potential when tested in accordance with the ASTM D4829 test method

(see Figures A5 through A9). These results are consistent with testing performed on nearby sites.

Based on these test results, the test results from previous studies referenced in this report and our local experience, the near-surface clay soils at the site are considered capable of exerting significant expansion pressures on building foundations, interior floor slabs, exterior flatwork, and pavements. In our opinion, the near surface soils supporting slab on grade concrete will require removal and replacement with imported, non-expansive soils (Expansion Index < 20), or chemical amendment of the clay soils (i.e., lime-treatment) to reduce the expansion potential of the near surface clays.

Liquefaction Potential

A common secondary hazard as a result of strong ground shaking is the potential for soil liquefaction and subsidence. Liquefaction describes a phenomenon in which saturated soil in the upper 40 to 50 feet of subgrade loses shear strength and deforms as a result of increased pore water pressure induced by strong ground shaking. As the excess pore pressures dissipate following an earthquake, volume changes within the liquefied soil layer will occur, which can manifest as ground surface settlement, ground rupture (sand boils or ground cracking), and lateral slope displacement (commonly referred to as lateral spreading). Soils most susceptible to liquefaction are saturated, loose to medium dense sand and silt or clay with plasticity indices (PI) less than 12 and moisture contents greater than 85 percent of the soils liquid limit (LL) (Bray and Sancio, 2006).

A preliminary screening suggests that a majority of the subsurface soils encountered during our investigation were generally too high in plasticity (i.e., clay) and/or too stiff/dense to be susceptible to liquefaction. Strata of silty sand, clayey sand and poorly graded “clean” sand, however, was encountered at borings D21 and D32 at depths of about 30 feet below the ground surface (bgs). Accordingly, a liquefaction analysis was performed in accordance with an approach outlined by the National Center for Earthquake Engineering Research (NCEER) and summarized by Youd, et al (2001). A groundwater depth of 12 feet (corresponding to the estimated high groundwater depth encountered), a peak ground acceleration adjusted for site class effects (PGAM) of 0.98g based on a return period of 2,475 years (2% probability of exceedance in 50 years), and a mode magnitude earthquake of 6.9 was used in the analysis. The mode magnitude earthquake was determined using the using the 2014 USGS National Seismic Hazard Mapping Project (NSHMP) Probabilistic Seismic Hazard Analysis (PSHA) Interactive Deaggregation website.

The results of our analysis suggest that strata of silty and poorly graded sands with penetration resistance (N-value) less than 30 blows per foot (bpf) and clayey sands with N-values less than about 20 bpf are potentially susceptible to liquefaction. Using empirical procedures (Ishihara and Yoshimine 1992), the seismically-induced settlement at the top of the liquefiable sand layers is estimated to range from about ¾ inch to 2 inches. This liquefaction is not expected to be widespread since the potentially liquefiable soil layers appear to be discontinuous and confined. Furthermore, ground surface settlement should be significantly less due to bridging effects within the overlying soil. Typical practice for these conditions is to assume a localized differential settlement on the order of one-half of the total estimated settlement to account for soil variability and engineering uncertainties. In our opinion, the anticipated maximum differential settlement due to liquefaction should be on the order of 1 inch over a horizontal distance of 100 feet.

The methods used to estimate liquefaction settlement assume that there is a sufficient cap of non-liquefiable material to prevent ground cracking or sand boils. For ground rupture to occur, the excess pore water pressure within the liquefiable soil layer needs to be great enough to break through the overlying non-liquefiable soil layer, which could cause additional ground deformation and settlement. The work of Youd and Garris (1995) indicates that the potentially liquefiable soils are overlain by a sufficient cap of non-liquefiable soil to prevent ground rupture; therefore the above total settlement estimates appear to be reasonable.

Seismic Site Class

Based on the soil conditions encountered at the exploration locations and our experience with similar soil conditions in the vicinity of the site, it is our opinion that the soils at the project site are not vulnerable to potential failure or collapse under seismic loading and can be designated as Site Class D in determining seismic design forces for this project in accordance with Section 1613A.3.2 of the 2013 CBC, which references Chapter 20 of American Society of Civil Engineers (ASCE) Standard 7-10. While relatively thin discrete layers of granular soils have been determined to be liquefiable, these layers appear to be discontinuous and confined. Furthermore, the estimated cumulative seismically induced settlement is relatively small (about 1 inch or less). In our opinion, the stiff clay soil profile under the site will control the seismic behavior of the soil in a seismic event.

2019 CBC/ASCE 7-16 Seismic Design Criteria

The 2019 CBC references the ASCE Standard 7-16 for seismic design. The following seismic parameters provided in Table 1 were determined based on the site latitude and longitude and the web interface developed by the Structural Engineers Association of California (SEAOC) and

the California Office of Statewide Health Planning and Development (OSHPD) (https://seismicmaps.org).

Since S_1 is greater than 0.2 g, a ground motion hazard analysis will be required (Section 11.4.8 of the 2019 CBC) in accordance with Section 21.2 of ASCE 7-16. However, if Exception Note No. 2 in Section 11.4.8 of ASCE 7-16 applies (specifically if $T \leq 1.5 \times T_s$), the 2019 CBC coefficient values F_v, S_{M1}, and S_{D1} presented in Table 1 below are valid for this project. Further evaluation of the seismic design parameters presented in Table 1, including the seismic Site Class will be required during preparation of the design-level geotechnical report.

The seismic design parameters summarized below in Table 1 may be used for seismic design of the planned improvement at the site.

TABLE 1 – 2019 CBC/ASCE 7-16 SEISMIC DESIGN PARAMETERS

* = The value is valid if the requirements in Exception Note No. 2 in Section 11.4.8 of ASCE 7-16 are met. If not, a ground motion hazard analysis will be required (Section 11.4.8 of the 2019 CBC) in accordance with Section 21.2 of ASCE 7-16

Bearing Capacity and Building Support

The subgrade soils encountered generally consist of stiff to hard, low compressible clay that should provide adequate support for the anticipated structural loading provided the recommendations in this report are followed. The surface and near-surface soils across the site were relatively loose and had frequent desiccation cracks ranging from about 6 to 18 inches in depth. Accordingly, these soils should be deep ripped or scarified, moisture conditioned, and compacted in-place prior construction and/or placement of engineered fill.

Groundwater

Groundwater was encountered in six of the 52 borings drilled during our field explorations, at depths ranging from approximately 12 to 20 feet below existing site grades. Review of available groundwater data revealed groundwater depths at the site likely fluctuated from about 10½ to 22 feet bgs.

Groundwater levels at the site should be expected to fluctuate throughout the year based on variations in seasonal precipitation, time of year, tidal fluctuations, local irrigation practices, and the proximity to drainage canals/ditches.

Based on explorations performed at the site and available groundwater data, we anticipate excavations extending below 10 feet below the ground surface may encounter groundwater and require dewatering (depending on the time of year).

Seasonal Water

During the wet season, infiltrating surface runoff water will create a saturated surface condition due to the relatively low permeability of the near-surface soils. It is probable that grading operations attempted following the onset of winter rains and prior to prolonged drying periods will be hampered by high soil moisture contents. Such soil, intended for use as engineered fill, will require a prolonged period of dry weather and/or considerable aeration to reach a moisture content that allows achieving the required compaction. This should be considered in the construction schedule for the project.

Pavement Subgrade Quality

Laboratory test results performed on three representative bulk samples of near-surface clay soils from proposed pavement areas of the site revealed these soils will provide poor support characteristics for pavements. Accordingly, relatively thick pavement sections are required to compensate for the lower support characteristics of these soils. Laboratory test results revealed

the clay soil possess a Resistance ("R") value of 5 when tested in accordance with California Test 301 (see Figures A10 through A12). Based on our findings and previous experience in the project area, it is our opinion an R-value of 5 is appropriate for design of pavements at the site supported on untreated subgrade soil.

In lieu of supporting pavement directly on expansive clay, pavement sections are also presented assuming the upper 12 inches of subgrade soil is amended by mixing it with lime (lime-treatment). This procedure strengthens and reduces the plasticity/expansion characteristics of the treated clay and, thus, tends to reduce future maintenance and associated costs. Furthermore, the required aggregate base section is thinner for pavement supported on lime treated soil, thus reducing the relative cost of the lime-treatment.

The performance of lime stabilized soils is dependent on uniform mixing of the quicklime into the subgrade soils, and providing a proper curing period following compaction. An experienced soil stabilization contractor, combined with a comprehensive quality control program, is essential to achieve the best results with lime stabilized soils.

Representative near-surface clay soils from proposed pavement areas of the site were mixed with four percent dolomitic quicklime and subjected to an R-value test. Laboratory test results revealed the treated clay soils possess an R-value of 82, 84, and 84 when tested in accordance with California Test 301 (see Figures A10 through A12). Based on the Caltrans Highway Design Manual, a maximum R-value of 50 should be used for design of pavements to be supported on a treated subgrade. Therefore, an R-value of 50 is appropriate for design of pavements at the site supported on treated surface and near-surface sand lean clay soils. Additional recommendations regarding lime-treatment of the pavement subgrade soils are provided in the Pavement Design section of this report.

Excavation Conditions

The surface and near-surface soils at the site should be readily excavated using conventional earthmoving and trenching equipment. Shallow excavations (less than 5-feet deep) in the clay encountered should stand vertically for a period long enough for typical foundation and utility, unless they become wet or are disturbed. The sand encountered, however, is cohesionless and may cave and/or slough soon after it is exposed in the excavation. Where encountered, the contractor should be prepared to brace or shore the excavations, as necessary.

Temporarily sloped excavations and shored excavations less than 20 feet in depth should be constructed in accordance with federal, local and OSHA standards (29 CFR Part 1926) under the guidance of the Contractors qualified “competent person.” For preliminary evaluation, the silts and clays encountered would classify as Cal-OSHA Type B soil, while the sands would

classify as Type C soils. In no case should the information provided be interpreted to mean that Wallace-Kuhl & Associates is assuming responsibility for site safety or the Contractor's activities.

Excavated materials should not be stockpiled directly adjacent to an open excavation to prevent surcharge loading of the excavation sidewalls. Excessive truck and equipment traffic should be avoided near excavations. If material is stored or heavy equipment is stationed and/or operated near an excavation, a shoring system must be designed to resist the additional pressure due to the superimposed loads.

Soil Suitability for Use in Fill Construction

The existing on-site soils, including the fill soils, are considered suitable for use as engineered fill, if they do not contain significant quantities of organics, rubble and deleterious debris, and are at a proper moisture content to achieve the desired degree of compaction. Organically laden topsoil should not be reused as engineered fill.

During the wet season, infiltrating surface runoff water will create a saturated surface condition due to the relatively low permeability of the near-surface soils. It is probable that grading operations attempted following the onset of winter rains and prior to prolonged drying periods will be hampered by high soil moisture contents. Such soil, intended for use as engineered fill, will require a prolonged period of dry weather and/or considerable aeration to reach a moisture content that allows achieving the required compaction. This should be considered in the construction schedule for the project.

Permeability Characteristics of Near-Surface Soils

The soils encountered in the area of the proposed detention ponds (borings D10, D11, D12, D18, D37, D43, D44, and D45) generally consisted of moderate to high plastic clay to depths ranging from about five to greater than 10 feet bgs, followed by silty and clayey sand. To assist in determining the permeability characteristics of the clays underlying the site, two laboratory hydraulic conductivity (ASTM D5084) tests were performed on relatively undisturbed soil samples obtained from borings D12 and D44. The results showed that the soil had permeability rates of about 9.8×10^{-9} and 1.7×10^{-6} centimeters per second (cm/sec.). The results are presented in Figures A13 and A14. Based on our previous experience, when compacted the permeability of these clays could be expected to be 1×10^{-7} cm/sec. or slower. Based on various publications (Hazen[1], Aryani[2] and Das[3]) and previous experience, for preliminary design a

[1] Allen Hazen, *Some Physical Properties of Sand and Gravels, with Special Reference to their Use in Filtration*, (Massachusetts: State Board of Health, 1892).

permeability rate of between $1x10^{-4}$ and $1x10^{-5}$ cm/sec can be anticipated for the silty and clayey sands encountered, respectively.

Depending on their final depths, we anticipate the ponds may need to be lined with clay to improve their "water-holding" capacity. The liner, if constructed, should be designed by the project Civil Engineer. As previously discussed, the native clays are moderate to highly plastic and may exhibit significant shrinking and cracking during warm weather conditions when the retention ponds are dry. When the ponds are again filled, the infiltration characteristics of the ponds could be affected for a period of time. If the native clay or a clay liner will be exposed within the ponds, consideration should be given to overlying the clays with a 12 to 18 inch thick layer of low plasticity silt or sand to reduce moisture fluctuations or by reducing the plasticity of the clay by intermixing or blending the soils with a low plasticity soils. If blending is considered, laboratory tests should be performed to evaluate the permeability of the mixed soil. If requested, WKA can provide additional criteria for either of these alternatives.

Soil Corrosion Potential

The samples of representative, near-surface clay soil was submitted to Sunland Analytical Lab of Rancho Cordova, California for laboratory testing to determine minimum resistivity, pH, and chloride and sulfate concentrations to help evaluate the potential for corrosive attack upon reinforced concrete and buried metal. The results of the corrosivity testing are summarized in Table 2; copies of the corrosion test reports are presented in Figures A15 through A26.

Table 2a: Corrosion Test Results

Analyte	Test Method	D6 (0'-5')	D14 (0'-5')	D22 (0'-5')
pH	CA DOT 643 Modified*	6.48	6.89	5.41
Minimum Resistivity	CA DOT 643 Modified*	540 Ω-cm	220 Ω-cm	880 Ω-cm
Chloride	CA DOT 422	323.0 ppm	758.8 ppm	61.6 ppm
Sulfate	CA DOT 417	167.4 ppm	821.2 ppm	185.2 ppm
Sulfate-SO4	ASTM D-516m	179.4 mg/kg	783.1 mg/kg	194.2 mg/kg

Ω-cm = Ohm-centimeters ppm = Parts per million

The California Department of Transportation Corrosion and Structural Concrete Field Investigation Branch, *Corrosion Guidelines*, Version 2.1, dated January 2015, considers a site to be corrosive to foundation elements if one or more of the following conditions exists for the representative soil and/or water samples taken: has a chloride concentration greater than or equal to 500 ppm, sulfate concentration greater than or equal to 2000 ppm, or the pH is 5.5 or less. Based on this criterion, areas of the on-site, near-surface clay soil are considered unusually corrosive to steel reinforcement properly embedded within PCC for the samples tested. The low resistivity may indicate a higher corrosion potential to metal in direct contact with soil. Based on the chloride concentration criterion, the surface and near-surface clay soils tested can lead to corrosion of steel reinforcement in concrete and steel structures by breaking down the protective layer of oxides normally present on the steel surface.

Caltrans indicates soil or water with a pH of 5.5 or less can react with the lime in concrete to form soluble reaction products that can more easily leach out of the concrete. This is of special concern where the sulfate concentrations in the soil are above 2,000 ppm, as the more brittle concrete (caused by the leaching of soluble reaction products) can be more susceptible to cracking which can allow for sulfate attack of the rebar reinforcement. Test results indicate a maximum sulfate concentration of 821.2 ppm at the site, which is well below the 2,000 ppm threshold. Acidic (low pH) conditions also can cause discoloration resulting in a yellowish or rust color distributed over the concrete surface. Considering the low sulfate concentrations, we do not anticipate the low pH of the soils to be a significant factor in development of the property.

Table 19.3.1.1 – Exposure Categories and Classes, of American Concrete Institute (ACI) 318-14, Section 19.3 – Concrete Design and Durability Requirements, as referenced in Section 1904.1 of the 2016 CBC, indicates the severity of sulfate exposure for the samples tested is Exposure Class S0 (water-soluble sulfate concentration in contact with concrete is low and

injurious sulfate attack is not a concern). The project structural engineer should evaluate the requirements of ACI 318-14 and determine their applicability to the site.

Wallace-Kuhl & Associates are not corrosion engineers. Therefore, if it is desired to further define the soil corrosion potential at the site a corrosion engineer should be consulted.

RECOMMENDATIONS

General

The recommendations presented below are appropriate for typical construction in the late spring through fall months. The on-site soils likely will be saturated by rainfall in the winter and early spring months, and will likely not be compactable without drying by aeration or chemical treatment. Should the construction schedule require work to continue during the wet months, additional recommendations can be provided, as conditions dictate.

Relative compaction should be based on the maximum dry density as determined in accordance with the ASTM D1557 Test Method.

Site preparation should be accomplished in accordance with the provisions of this report and the appended specifications. A representative of the Geotechnical Engineer should be present during all earthwork operations to evaluate compliance with the recommendations and the guide specifications included in this report. The Geotechnical Engineer of Record referenced herein should be considered the Geotechnical Engineer that is retained to provide geotechnical engineering observation and testing services during construction.

Site Clearing

Prior to grading, the planned construction areas should be cleared of all surface trash, rubble, and deleterious debris, if any, to expose firm and stable soils, as determined by the Geotechnical Engineer's representative. The area of removal should extend at least five feet beyond the edge of all exterior flatwork and pavements, where practical. Any rubble and debris, if encountered, should be removed from the site.

Any existing underground utilities designated to be removed or relocated from the site should include removal of all trench backfill and bedding materials. The resulting excavations should be restored with engineered fill placed and compacted in accordance with the recommendations included in this report.

Surface vegetation/organics and organically laden soil within construction areas should be stripped from the site. Debris from the stripping operations should not be used in general fill construction areas supporting concrete slabs, pavements or any other surface improvements. Discing of the organics into the surface soils may be a suitable alternate to stripping, depending on the condition and quantity of the organics at the time of grading. The decision to utilize discing in lieu of stripping should be made by the Geotechnical Engineer, or his representative, at the time of earthwork construction. Discing operations, if approved, should be observed by the Geotechnical Engineer's representative, and be continuous until the organics are adequately mixed into the surface soils to provide a compactable mixture of soil containing minor amounts of organic matter. Pockets or concentrations of organics will not be allowed.

Any depressions resulting from site clearing operations, as well as any loose, soft, disturbed, saturated, or organically contaminated soils, as identified by the Geotechnical Engineer's representative, should be cleaned out to firm, undisturbed soils and backfilled with engineered fill in accordance with the recommendations of this report. It is important that the Geotechnical Engineer's representative be present during clearing operations to verify adequate removal of any surface and subsurface items, as well as the proper backfilling of resulting excavations.

Site Preparation

The near-surface soil underlying the site consists of moderate to highly plastic clay that, based on our experience and testing, can exhibit significant expansion characteristics. The following presents recommendations for general subgrade preparation. Subsequent sections should be reviewed for specific or supplemental recommendations to address the expansive soil conditions.

The surface and near-surface soils encountered during our investigation were relatively loose with frequent desiccation cracks. Furthermore, we anticipate that clearing operations will likely cause additional disturbance to the upper soils. Therefore, in all areas that will support concrete slabs, engineered fill or pavement, should be thoroughly scarified to a depth of at least 12 inches, brought to a uniform moisture content at least two percentage point above the optimum moisture content, and compacted to not less than 90 percent of the maximum dry density per ASTM D1557 specifications. In pavement areas, the relative compaction of the upper 6 inches of final soil subgrade should be increased to 95 percent of the maximum dry density.

The performance of pavement is critically dependent upon uniform and adequate compaction of the soil subgrade, as well as all engineered fill and utility trench backfill within the limits of the pavements. Final pavement subgrade preparation (i.e. scarification, moisture conditioning and compaction) should be performed after underground utility construction is completed and just prior to aggregate base placement.

Pavement subgrades should be stable and unyielding under heavy wheel loads of construction equipment. To help identify unstable subgrades within the pavement limits, a proof-roll should be performed with a fully-loaded, water truck on the exposed subgrades prior to placement of aggregate base. The proof-roll should be observed by the Geotechnical Engineer's representative.

If construction begins during the summer or fall, there is a potential that the surface clayey soils may be desiccated deeper than the recommended depth of scarification. Should this condition exist, the site should be continuously watered for a sufficient period of time to close the desiccation cracks.

The prepared subgrade soils should be protected from disturbance until covered by capillary break material or aggregate base. Disturbed subgrade soils may require additional processing and recompaction just prior to construction of these improvements, depending on the level of disturbance.

All subgrade preparation must be performed in the presence of the Geotechnical Engineer's representative who will evaluate the performance of the subgrade under compaction loads and identify any loose or unstable soil conditions that could require remediation. Construction bid documents should contain a unit price (price per cubic foot) for additional excavation due to unsuitable materials and replacement with engineered fill.

Engineered Fill Construction

Engineered fill consisting of on-site or import materials should be placed in lifts not exceeding six inches in compacted thickness, with each lift being thoroughly moisture conditioned to at least two percent above the optimum moisture content for clay soils and to the optimum moisture content for granular/silty soils (import fill materials). Soils should be uniformly compacted to at least 90 percent relative compaction.

On-site soils encountered in our explorations are considered suitable for use as engineered fill, provided they are at a workable moisture content to achieve required compaction, and do not contain rubbish, rubble, deleterious debris, and organics. However, clay soils should not be used in fills within the upper 12 inches of final subgrade for the building pad or exterior flatwork, unless the clay soils are lime-treated as described in the Lime Treatment Alternative section of this report.

Imported fill materials should be compactable, well-graded, granular soils with a Plasticity Index of 15 or less when tested in accordance with ASTM D4318; an Expansion Index of 20 or less when tested in accordance with ASTM D4829, and should not contain particles greater than

three inches in maximum dimension. In addition, we recommend that the contractor supply a certification for any imported fill materials that designates the fill materials do not contain known contaminants per Department of Toxic Substances Control's guidelines for clean fill, and have corrosion characteristics within acceptable limits. Imported soils should be approved by the Geotechnical Engineer prior to being transported to the site.

All earthwork operations should be accomplished in accordance with the recommendations contained within this report and the *Guide Earthwork Specifications* provided in Appendix B. We recommend the Geotechnical Engineer's representative be present on a regular basis during all earthwork operations to observe and test the engineered fill and to verify compliance with the recommendations of this report and the project plans and specifications.

Cut and Fill Slopes

We anticipate that cut and fill slopes less than 10 feet in vertical height may be constructed to provide level building areas. In our professional opinion, fill slopes should be inclined no steeper than 2(h):1(v). This slope recommendation is based on our experience with similar conditions since no detailed slope stability analysis was performed to justify steeper slopes. Given this inclination, however, there is a modest risk that displacement, movement, and/or soil sloughing could occur in the event of strong seismic ground shaking. For the native soils and compacted fill conditions anticipated, we expect this movement to be relatively shallow, requiring limited cleanup and dressing to restore the slopes to their original condition. If this risk is unacceptable to the owner, the slopes should be flattened to 3(h):1(v) or flatter.

Since the proposed detention pond embankments will be immersed below water, the embankments should be constructed at an inclination of 3(h):1(v) or flatter. Like discussed above, some shallow seated displacement or movement should be anticipated in the event of strong seismic ground shaking. If this condition is unacceptable, the embankments should be flattened.

Paved interceptor drains should be provided along the tops of slopes where the tributary area flowing toward the slope has a drainage path greater than 40 feet, measured horizontally. The interceptor drains or terraces should be sloped to a suitable drainage device and disposed off-site well below the toe of the slope. Drop inlets and storm sewers should not be installed near the crests of slopes because leakage can result in maintenance problems or possible slope failure. The slopes should be inspected periodically for erosion, and if detected, repaired immediately. To reduce erosion and gulling, all disturbed areas should be planted with erosion-resistant vegetation suited to the area. As an alternative, jute netting or geotextile erosion control mats can be installed per the manufacturer's recommendations. Slopes should be over-built and cutback to design grades and inclinations.

Utility Trench Backfill

Utility trench backfill within structural areas (e.g. building, exterior flatwork, pavements, etc.) should be mechanically compacted as engineered fill in accordance with the following recommendations. Bedding and initial backfill around and over the pipe should conform to the pipe manufacturer's recommendations and applicable sections of the governing agency standards.

Based on explorations performed at the site and available groundwater data, we anticipate excavations extending below 10 feet below site grade may encounter groundwater (depending on the time of year) and may require dewatering. Where groundwater is encountered, the use of sumps, submersible pumps, deep wells or a well point system could be used as methods to lower the groundwater level. The dewatering method used will depend on the soil conditions, depth of the excavation and amount of groundwater present within the excavation. Dewatering, if required, should be the contractor's responsibility. The dewatering system should be designed and constructed by a dewatering contractor with local experience. We recommend the selected dewatering system lower the groundwater level to at least two feet below the bottom of the proposed excavations.

It is likely that materials excavated from trenches will be at elevated moisture contents and will require significant aeration or a period of drying to reach a compactable moisture content. We recommend bid documents contain a unit price for the removal and drying of saturated soils, or replacement with approved import soils.

We recommend that on-site soil be used as trench backfill, especially below the non-expansive or lime-treated material within the footprint of the interior concrete slabs. Utility trench backfill should be placed in maximum eight-inch lifts (compacted thickness), thoroughly moisture conditioned to at least two percent above the optimum moisture content, and mechanically compacted to at least 90 percent relative compaction. Within the upper 12 inches of final subgrade for the interior concrete slabs and exterior flatwork, trench backfill should consist of granular material placed and compacted as described in the Engineered Fill Construction section of this report, unless the lime-treatment alternative is selected. Where the top 12 inches of the interior concrete slabs and exterior flatwork areas consist of lime-treated soils, the upper 12 inches of trench backfill should consist of controlled density fill (CDF) or aggregate base compacted to at least 95 percent relative compaction. Within the upper six inches of untreated pavement subgrade soils and upper 12 inches of lime-treated pavement subgrade soils, compaction should be increased to at least 95 percent relative compaction at no less than two percent above the optimum moisture content.

We recommend that all underground utility trenches aligned nearly parallel with new foundations be at least three feet from the outer edge of foundations, wherever possible. Trenches should not encroach into the zone extending outward at a one horizontal to one vertical (1H:1V) inclination below the bottom of foundations. Additionally, trenches parallel to existing foundations should not remain open longer than 72 hours. The intent of these recommendations is to prevent loss of both lateral and vertical support of foundations, resulting in possible settlement.

Foundations

The proposed structures may be supported upon continuous and/or isolated spread foundations. Due to expansive soil considerations, the foundations should extend at least 18 inches below lowest adjacent soil grade. Lowest adjacent soil grade is defined as the grade upon which the capillary break material is placed or exterior soil grade, whichever is lower. Continuous foundations supporting should maintain minimum widths of 15; while isolated spread foundations should be at least 24 inches in plan dimension. Foundations should be continuous around the perimeter of the building to reduce moisture variations beneath the structures. If shrinkage cracks appear in the footing excavations, the excavations should be thoroughly moistened to close all cracks prior to placement of concrete.

Foundations bearing on undisturbed or compacted native soils, engineered fill, or a combination of those materials may be sized for maximum allowable “net” soil bearing pressure of 3,000 pounds per square foot (psf) for dead plus live load. A one-third increase in the allowable bearing pressure may be applied when considering short-term loading due to wind or seismic forces. The weight of the foundation concrete extending below lowest adjacent soil grade may be disregarded in sizing computations.

Total settlement of an individual foundation will vary depending on the plan dimensions of the foundation and the actual load supported. Based on the foundation criteria discussed above and the assumed foundation loads, foundations are anticipated to experience a maximum total static settlement on the order of about ¾ to 1 inch, and differential settlement on the order of about ½ inch for 50 lineal feet or the shortest distance of the structure, whichever is less.

As discussed in the Liquefaction Potential section of the Conclusions, it is estimated that up to 1 inch of differential settlement over a horizontal distance of 100 feet could occur in the event of strong ground shaking (earthquake with a return period of 2,475 years or 2% probability of exceedance in 50 years).

All foundations be adequately reinforced to provide structural continuity, mitigate cracking and permit spanning of local soil irregularities. The structural engineer should determine final foundation reinforcing requirements.

Resistance to lateral foundation displacement may be computed using an allowable friction factor of 0.30, which may be multiplied by the effective vertical load on each foundation. Additional lateral resistance may be computed using an allowable passive earth pressure equivalent to a fluid pressure of 300 psf per foot of depth, acting against the vertical projection of the foundation. These two modes of resistance should not be added together unless the frictional component is reduced by 50 percent since full mobilization of the passive resistance requires some horizontal movement, effectively reducing the frictional resistance. We recommend that all foundation excavations be observed by the Geotechnical Engineer's representative prior to placement of reinforcement and concrete to verify firm bearing materials are exposed.

Interior Floor Slabs

Conventional floor slabs in combination with shallow spread foundations may be used for support of the proposed structures. As discussed in the Soil Expansion Potential section of the Conclusions, the near-surface soil underlying the site and anticipated clay fill can exhibit significant expansion characteristics.

The most direct method to reduce expansive soil risks and improve the subgrade conditions would be to support the proposed floor slabs on a layer of compacted, non-expansive fill. This procedure consists of placing at least 12 inches of non-expansive fill directly below the proposed floor slab system. The non-expansive fill should be moisture conditioned to at or above its optimum moisture content and compacted as engineered fill. Specific requirements for import fill are presented in the Engineered Fill section. The non-expansive soil pads could be prepared by removing and replacing the native clay, raising the building pads above existing site grade, or a combination of both. A capillary break or other slab support system placed directly below the floor slabs should not replace in whole or part the non-expansive fill layer. The zone of non-expansive soil should extend laterally at least 3 feet outside the perimeter of the structures. Prior to placement of the non-expansive fill, the moisture content of the underlying clay soil should be checked. If the soil moisture content is found to be less than1 percentage point above the optimum moisture content, the soil moisture content should be raised using liberal sprinkling, flooding or another suitable method. A representative of the Geotechnical Engineer should perform a field check of the soil moisture content and relative compaction prior to placement of the non-expansive fill.

A second approach (lime treatment) consists of mixing the upper 12 inches of subgrade soils within the proposed floor slab area with dolomitic or high calcium quick lime and compacting the soil as engineered fill. The subgrade preparation, spreading, mixing, compacting and lime type should meet the requirements outlined in Section 24 of the Caltrans Standard Specifications. The zone of lime-treated soil should extend laterally at least 3 feet outside the perimeter of the proposed structure. Based on our previous experience, 4½ pounds of quick lime per cubic foot of soil may be assumed for planning purposes. The lime treated subgrade soils should be compacted to at least 90 percent relative compaction.

At least 2 to 3 days prior to spreading or mixing the lime, the moisture content of the underlying, untreated clay soil should be checked. If the soil moisture content is found to be dry of optimum, the soil moisture content should be raised using liberal sprinkling, flooding or another suitable method. A representative of the Geotechnical Engineer should be on-site during treatment operations to document spreading, mixing and compaction operations and provide supplemental/revised recommendations, if warranted, based on the soil conditions observed.

Following lime treatment, the treated soil should be properly cured by continual sprinkling with water to keep the surface damp, combined with light rolling to keep the surface knitted together. We suggest that the subgrade soils be covered with Class 2 aggregate base or crushed rock within 2 to 3 days of lime treatment in an effort to reduce drying. Periodic sprinkling is still required to keep the surface damp. As an alternative, the treated soil could be cured as discussed in Section 24 of the Caltrans Standard Specifications.

Lime treatment increases the pH of the soil and may not promote plant growth. Accordingly, the landscape designer should be consulted during pre-construction to verify that future landscaping is suitable for lime treated soils. If the landscaping is not suitable, the lime-treated soils should be completely removed and replaced prior to planting.

The interior concrete slabs should be at least four inches thick, however, the project structural or civil engineer should determine final floor slab thickness, reinforcement and joint spacing. Temporary loads exerted during construction from vehicle traffic, cranes, forklifts, other construction equipment, rack loads, and storage of palletized construction materials, etc. should be considered in the design of the thickness and reinforcement of the interior concrete slabs-on-grade.

Provided the building pad is constructed in accordance with the recommendations included in this report (12 inches of non-expansive, granular soils or lime-treated clay soils, and six inches of aggregate base where applicable), a soil modulus of reaction (k_s) of 200 kips per cubic foot (kcf) or 115 pounds per cubic inch (pci) may be utilized for design of floor slabs subjected to vehicle/fork lift traffic or any other loading conditions described above.

Moisture Penetration Resistance

It is likely that the subgrade soils below floor slabs will become very moist or wet at some time during the life of the structures. This is a certainty if the subgrade soils are constructed during the wet season or poor drainage conditions exist adjacent to structures. For this reason, it should be assumed that interior floor slabs with moisture-sensitive floor coverings or coatings will require protection against moisture or moisture vapor penetration through the slabs.

Interior floor slabs for the planned buildings should, as a minimum, be underlain by a layer of free-draining crushed rock/gravel, serving as a deterrent to migration of capillary moisture. The crushed rock/gravel layer should be between four- and six-inches-thick and graded such that 100 percent passes a one-inch sieve and less than five percent passes a No. 4 sieve. Additional moisture protection may be provided by placing a vapor retarder membrane (at least 10-mils thick) directly over the crushed rock/gravel. The water vapor retarder membrane should meet or exceed the minimum specifications as outlined in ASTM E1745 and be installed in strict conformance with the manufacturer's recommendations. For warehouse portions of the proposed buildings that will not have moisture-sensitive floor coverings or coatings, the vapor retarder membrane should be placed directly over 4 to 6 inches of compacted aggregate base.

Floor slab construction practice over the past 30 years or more has included placement of a thin layer of dry sand or pea gravel over the vapor retarder membrane. The intent of the sand/pea gravel is to aid in the proper curing of the slab concrete. However, during the wet seasons moisture can become trapped in the sand or pea gravel, which can lead to excessive moisture vapor emissions from floor slabs. As a consequence, we consider use of the sand/pea gravel layer as optional. The concrete curing benefits should be weighed against efforts to reduce slab moisture vapor transmission.

It is emphasized that the crushed rock/grave and the vapor retarder membrane suggested above provides only a limited, first line of defense against soil-related moisture issues and will not "moisture proof" the slab. Nor do these measures provide an assurance that slab moisture transmission levels will be within tolerable levels to prevent damage to floor coverings or other building components. If increased protection against moisture vapor penetration is desired, a concrete moisture protection specialist should be consulted. The design team should consider all available measures for slab moisture protection. It is commonly accepted that maintaining the lowest practical water-cement ratio in the slab concrete is one of the most effective ways to reduce future moisture vapor penetration of the completed slabs.

Retaining Walls

All retaining walls or below grade walls for the buildings should be designed to resist the lateral soil pressures of the retained soils. Retaining walls that are fixed/restrained at the top should be capable of resisting an “at-rest” lateral soil pressure equal to an equivalent fluid pressure of 60 psf per foot of the wall height (fully drained conditions). Retaining walls above the estimated high groundwater level that will be allowed to slightly rotate about their base (unrestrained at the top or sides) should be capable of resisting an "active" lateral soil pressure equal to an equivalent fluid pressure of 40 psf per foot of wall height (fully drained conditions),

If structural elements, i.e., foundations, roadways, etc., encroach the one horizontal to one vertical (1H:1V) projection from the bottom of retaining walls, the retaining walls should account for surcharge loads resulting from those structural elements. Additionally, any below-grade retaining walls should also account for surcharge loads resulting from construction equipment, vehicles, palletized materials, etc. that encroach the one horizontal to one vertical (1H:1V) projection from the bottom of the below-grade retaining walls. Surcharge loading under the circumstances described above should be evaluated by the retaining wall designer on a case-by-case basis and be included in their design of the walls. The retaining wall designer should evaluate the surcharge load distribution, magnitude of the surcharge resultant force to be applied on the walls, and the location of where the resultant force should be applied on the walls. Surcharge loading on the retaining walls will depend on the specific surcharge load type (e.g. point load, distributed load, etc.) and distance away from the retaining walls.

Retaining wall or below grade walls should be fully drained to prevent the build-up of hydrostatic pressures behind the wall. Retaining walls should be provided with a drainage blanket of Class 2 permeable material, Caltrans Standard Specification, Section 68-2.02F(3), at least one foot wide extending from the base of wall to within one foot of the top of the wall. The top foot above the drainage layer should consist of compacted on-site or imported engineered fill materials, unless covered by a concrete slab or pavement. Weep holes or perforated rigid pipe, as appropriate, should be provided at the base of the wall to collect accumulated water. Drainpipes, if used, should slope to discharge at no less than a one percent fall to suitable drainage facilities. Open-graded ½ to ¾ inch crushed rock may be used in lieu of the Class 2 permeable material provided the rock and drain pipe are completely enveloped in an approved non-woven, geotextile filter fabric. Alternatively, approved geotextile drainage composites, such as MiraDRAIN®, may be used in lieu of the drain rock layer. If used, geocomposite drain panels should be installed in accordance with the manufacturer’s recommendations.

If efflorescence (discoloration of the wall face) or moisture/water penetration of the retaining walls is not acceptable, moisture/water-proofing measures should be applied to the back face of the walls. A moisture/water-proofing specialist should be consulted to determine specific protection measures against moisture/water penetration through the walls.

Structural backfill materials for retaining walls within a one horizontal to one vertical (1H:1V) projection from the bottom of the walls (other than the drainage layer) should consist of imported, granular material or native sand and silt that does not contain significant quantities of rubbish, rubble, organics and rock over four inches in size. Clay, pea gravel and/or crushed rock should not be used for structural wall backfill. Structural wall backfill should be placed, moisture conditioned and compacted in accordance with recommendations provided in the Engineered Fill section of this report.

Foundations for support of retaining or below grade walls should be designed using the appropriate foundation design parameters provided in the Foundations section included in this report.

Exterior Flatwork

The final subgrade for exterior concrete flatwork (i.e., sidewalks, patios, etc.) should be prepared and constructed in accordance with recommendation provided in the Interior Floor Slab section above. The zone of non-expansive fill or lime-treated soils can be reduced to at least 1 foot laterally outside the perimeter of the flatwork.

As an alternative, the subgrade soils could be presoaked by wetting and pre-swelling the subgrade soils prior to placement of concrete, thus reducing the potential for post-construction movement. This approach tends to be the less costly, however, the risk for isolated heaving and cracking is greater since it can be difficult to uniformly moisture condition and completely pre-swell the subgrade soil prior to placement of concrete. Furthermore, pre-soaking also softens and weakens the clay, making this this approach not appropriate where flatwork will support vehicular traffic, heavy concentrated loads, heavy equipment or machinery due to settlement and bearing concerns.

Following subgrade preparation, presoaking consists of wetting or soaking the upper 18 inches of final soil subgrade in order to uniformly raise the soils' moisture content to a uniform, near-saturated moisture condition. The zone of wetting should extend laterally at least one foot outside the perimeter of the flatwork. Presoaking is usually performed using liberal sprinkling, flooding, or other suitable method. The time required for pre-soaking could vary from a few days to over a week depending on the condition of the subgrade soils. If the exposed soils are kept moist or wet following subgrade preparation, the amount and time required for presoaking

is often reduced. Likewise, restricting vehicle or equipment traffic following earthwork will decrease the potential for over-compacting the soils and reducing the ability for water to penetrate. A representative of the Geotechnical Engineer should perform a field check of the soil's moisture content and consistency within three days of concrete placement. In hot and/or windy weather, the field moisture check should be performed within 24 hours of concrete placement.

The exterior flatwork concrete should be at least four inches thick and underlain by at least four inches of aggregate base compacted to at least 95 percent relative compaction to provide stability during slab construction and to protect the soils from disturbance during construction. Consideration should be given to thickening the edges of the slabs at least twice the slab thickness where wheel traffic is expected over the slabs. Expansion joints should be provided to allow for minor vertical movement of the flatwork. Exterior flatwork should be constructed independent of other structural elements by the placement of a layer of felt material between the flatwork and the structural element. The slab designer should determine the final thickness, strength and joint spacing of exterior slab-on-grade concrete. The slab designer should also determine if slab reinforcement for crack control is required and determine final slab reinforcing requirements.

Because of seasonal wetting and drying or irrigation of the soil, isolated differential movement and cracking sometimes forms along the outside edges of exterior flatwork. To reduce this risk, consideration should be given placing lateral cutoffs along the outside edges of the flatwork, doweling joints to reduce tripping hazards, and/or stiffening the flatwork by increasing the concrete thickness and including reinforcing steel.

Areas adjacent to new exterior flatwork should be landscaped to maintain more uniform soil moisture conditions adjacent to and beneath flatwork. Final landscaping plans not allow fallow ground adjacent to exterior concrete flatwork.

Practices recommended by the Portland Cement Association (PCA) for proper placement, curing, joint depth and spacing, construction, and placement of concrete should be followed during exterior concrete flatwork construction.

Site Drainage

Final site grading should be accomplished to provide positive drainage of surface water away from the buildings and prevent ponding of water adjacent to foundations, slabs or pavements. The subgrade adjacent to the buildings should be sloped away from foundations at a minimum two percent gradient for at least 10 feet, where possible. We recommend connecting all roof drains to solid drainage pipes which are connected to available drainage features that convey

water away from the buildings, or discharging the drains onto paved or hard surfaces that slope away from the foundations. Discharging or ponding of surface water should not be allowed adjacent to the building, exterior flatwork or pavements. Landscape berms, if planned, should not be constructed in such a manner as to promote drainage toward the buildings.

Pavement Design

The subgrade soils in pavement areas should be prepared and constructed in accordance with recommendations provided in the Subgrade Preparation and Engineered Fill sections. All aggregate base should be compacted to at least 95 relative compaction.

The moisture content of the prepared subgrade soils should be maintained until placement of the aggregate base by periodic sprinkling with water or other suitable method. If there is a delay between placing the aggregate base and asphalt-concrete, the aggregate base should also be periodically sprinkled or wetted to prevent drying of the underlying soil subgrade. A field check of the subgrade soils moisture condition should be performed by the Geotechnical Engineer's representative prior to placement of the aggregate base.

As an alternative, the upper 12 inches of subgrade soil can be stabilized by mixing it with dolomitic or high calcium quick lime (lime-treatment). The subgrade preparation, spreading, mixing, compacting, lime type and curing should meet the criteria discussed in the Interior Floor Slab section. The zone of lime-treated soil should extend laterally at least two feet outside the perimeter of the proposed pavement subgrade. The lime-treated subgrade soil should be compacted to at least 95 percent relative compaction. A representative of the Geotechnical Engineer should be on-site during treatment operations to document spreading, mixing and compaction operations and provide supplemental/revised recommendations, if warranted, based on the soil conditions observed.

Based on laboratory testing results and previous nearby experience, an R-value of 5 was used for design of pavements supported on compacted native clay and an R-value of 50 was used for lime treated clays. The pavement sections presented in Table 3 have been calculated using traffic indices assumed to be appropriate for the project using pavement design criteria outlined in Chapters 600 to 670 of the *California Highway Design Manual* (Caltrans, 2019), and Sacramento County, November 1, 2009 Street Design Standards. The project civil engineer should determine the appropriate traffic index and pavement section based on anticipated traffic conditions. If needed, we can provide alternative pavement sections for different traffic indices.

Table 3: On-site Pavement Design Alternatives

Traffic Index (TI)	Pavement Use	Untreated Subgrades R-value = 5			Lime-Treated Subgrades Soils (**) R-value = 50		
		Type A Asphalt Concrete (inches)	Class 2 Aggregate Base (inches)	Portland Cement Concrete (inches)	Type A Asphalt Concrete (inches)	Class 2 Aggregate Base (inches)	Portland Cement Concrete (inches)
4.5	Light Automobile Parking Only	2½*	10	--	2½*	4	--
		3*	8	--	3*	4	--
		--	4	6	--	4	4
6.5	Automobile, Light 2- to 3-axle Truck Traffic, Fire Lanes and Trash	3	16	--	3*	4	--
		4*	14	--	4*	4	--
		--	6	6	--	5	4
8.0	Light-Moderate 4-axle-Truck Traffic	3½	20	--	3½	9	--
		5*	18	--	5*	6	--
		--	7	6	--	6	4
9	Moderate-Heavy 5-axle-Truck Traffic (AADTT ≈ 75)	4½	22	--	4½	11	--
		5½*	21	--	5½*	9	--
		--	8	8	--	6½	4
10.0	Heavy 5-axle-Truck Traffic (AADTT ≈ 170)	5	25	--	5	13	--
		6½*	23	--	6½*	11	--
		--	8	10	--	7½	6

* = Asphalt concrete thickness contains the Caltrans safety factor.

**= Lime-treated subgrade should be at least 12 inches thick and possess a minimum R-value of 40 when testing in accordance with California Test 301.

AADTT = Annual Average Daily Truck Traffic, assuming 5-axles trucks and 20-year ESAL Constant.

In the summer heat, high axle loads coupled with shear stresses induced by sharply turning tire movements can lead to failure in asphalt concrete pavements. Therefore, we recommend that consideration be given to using Portland concrete cement (PCC) pavements in areas subjected to concentrated heavy wheel loading, such as entry driveways and in front of trash enclosures. Alternate PCC pavement sections have been provided above in Table 3. All aggregate base should be compacted to at least 95 percent relative compaction.

We suggest the concrete slabs be constructed with thickened edges in accordance with American Concrete Institute (ACI) design standards, latest edition. Reinforcing for crack control, should be provided in accordance with ACI guidelines. Reinforcement must be located at mid-slab depth to be effective. Joint spacing and details should conform to the current PCA or ACI guidelines. Per the California Highway Design manual, PCC should achieve a minimum modulus of rupture/flexural strength of 625 pounds per square inch (psi) at 28 days. Per PCA guidelines, a minimum compressive strength of 4,000 psi at 28 days is required to achieve the specified modulus of rupture.

All pavement materials and construction methods of structural pavement sections should conform to the applicable provisions of the Caltrans Standard Specifications and Napa County Standards, latest editions.

Efficient drainage of all surface water to avoid infiltration and saturation of the supporting aggregate base and subgrade soils is important to pavement performance. Weep holes could be provided at drainage inlets, located at the subgrade-aggregate base interface, to allow accumulated water to drain from beneath the pavements.

Consideration should be given to using full-depth curbs between landscaped areas and pavements to serve as a cut-off for water that could migrate into the pavement base materials or subgrade soils.

Ancillary Foundations

Foundations for lightly-loaded, ancillary structures not structurally connected to the proposed buildings, such as sound walls, landscape walls, monuments, trash enclosures, or similar structures, may be supported upon conventional spread foundations or drilled, cast-in-place reinforced concrete piers (drilled piers). Drilled piers may be used for support of light poles or similar structures.

Conventional Spread Foundations

Conventional spread foundations should bear on firm, undisturbed ground, engineered fill, or a combination of these materials, as confirmed by the Geotechnical Engineer or his representative. The spread foundations should be at least 12 inches wide and extend at least 18 inches below the lowest adjacent soil grade. The foundations may be sized using a maximum allowable soil bearing pressure of 2,000 psf, with a one-third increase for wind or seismic forces. Lateral foundation resistance may be determined using the factors presented in the Foundations section. The upper 12 inches of subgrade soil should be disregarded when estimating lateral resistance.

Drilled, Cast-in-Place Concrete Piers

Drilled piers should be at least 18 inches in diameter, extend at least five feet below lowest adjacent soil grade, and sized using a maximum allowable end-bearing capacity of 4,000 psf or an allowable skin friction of 250 psf for dead plus live loads, which may be applied over the surface area of the pier. These values may be increased by one-third to include short-term wind or seismic forces. The weight of foundation concrete below grade may be disregarded in sizing computations.

Uplift resistance of drilled pier foundations may be computed using the following resisting forces, where applicable: 1) weight of the pier concrete and, 2) the allowable skin friction of 250 psf applied over the shaft area of the drilled pier. Increased uplift resistance can be achieved by increasing the diameter of the drilled pier or increasing the depth.

The upper 12 inches of skin friction should be neglected for axial capacity or uplift resistance unless the drilled pier is surrounded by slab concrete or pavements for a distance of at least three feet from the edge of the foundation.

Sizing of drilled piers to resist lateral loads can be evaluated using Section 1807.1 of the 2016 CBC. An allowable lateral soil bearing pressure of 200 psf per foot of depth may be used for the CBC parameters S_1 (equation 18-1) and S_3 (equations 18-2 and 18-3). If a deflection of ½ inch at the ground surface is acceptable, this value may be doubled. The upper 12 inches of the subgrade should be neglected when determining lateral resistance.

Reinforcement and concrete should be placed in the pier excavations as soon as possible after excavation is completed to reduce the potential for caving. In no case should the elapsed time between completion of the pier excavation and the start of concrete placement exceed 48 hours. If the piers are designed using the allowable vertical bearing pressure, the bottom of the pier excavations should be free of loose or disturbed soils prior to placement of the concrete. Cleaning of the bearing surface should be verified by the Geotechnical Engineer prior to concrete placement.

If drilled piers are designed using end-bearing capacity and seepage or groundwater is encountered, the water should be pumped from the pier excavation to allow inspection and concrete placement. Otherwise, the concrete should be placed using tremie methods from the bottom of the hole, while keeping the tremie pipe below the surface of the concrete at all times.

Site Drainage

Because of expansive soil concerns, the performance of foundations and concrete slabs relies on how well storm runoff and irrigation water drains from the site. Final site grading should be accomplished to provide positive drainage of surface water away from the buildings and prevent ponding of water adjacent to foundations, slabs or pavements. The subgrade adjacent to the buildings should be sloped away from the building at a minimum two percent gradient for at least five feet, where possible. All roof drains should be connected to non-perforated rigid pipes, which in-turn are connected to available drainage features that convey water away from the buildings or discharging the drainage onto paved or hard surfaces that slope away from the buildings. Landscape berms, if planned, should not be constructed in such a manner as to promote drainage toward the buildings.

Drought Considerations

The State of California can experience extended periods of severe drought conditions. Desiccated clay can shrink and crack and the ability for landowners to use irrigation as a means for maintaining landscape vegetation and soil moisture can be inhibited for unpredictable periods of time. For this reason, landscape and hardscape systems for this development should be carefully planned to prevent the desiccation of soils under and near foundations and slabs. Trees with invasive shallow root systems should be avoided. No trees or large shrubs that could remove soil moisture during dry periods should be planted within five feet of any foundation or slab. Fallow ground adjacent to foundations must be avoided.

To reduce potential for soil creep adversely affecting foundations or exterior flatwork, we recommend a minimum horizontal distance of five feet be provided and maintained between the outside edge of the foundation or flatwork to the nearest adjacent slope (e.g. building pad hinge point), for slopes greater than two feet in height.

Geotechnical Engineering Observation and Testing During Earthwork Construction

Site preparation should be accomplished in accordance with the recommendations of this report and the *Guide Earthwork Specifications* provided in Appendix D. Geotechnical testing and observation during construction is considered a continuation of our geotechnical engineering investigation. Wallace-Kuhl & Associates should be retained to provide testing and observation services during site clearing, preparation, earthwork, and foundation construction at the project to verify compliance with this geotechnical report and the project plans and specifications, and to provide consultation as required during construction. These services are beyond the scope of work authorized for this investigation; however, we would be pleased to submit a proposal to provide these services upon request.

Section 1803.5.8 “Compacted Fill Material” of the 2016 CBC requires that the geotechnical engineering report provide a number and frequency of field compaction tests to determine compliance with the recommended minimum compaction. Many factors can affect the number of tests that should be performed during construction, such as soil type, soil moisture, season of the year and contractor operations/performance. Therefore, it is crucial that the actual number and frequency of testing be determined by the Geotechnical Engineer during construction based on their observations, site conditions, and difficulties encountered. As a preliminary guideline, we recommend the following minimum tests:

- mass grading: one test per 500 cubic yards of compacted fill or one per day of work, whichever is greater
- final subgrade preparation: one test per 5,000 square feet
- aggregate base compaction: one test per 5,000 square feet
- utility backfill: one test per foot of backfill for every 150 linear feet of trench
- wall backfill: one test per foot of backfill for every 100 linear feet of wall

In the event that Wallace-Kuhl & Associates is not retained to provide geotechnical engineering observation and testing services during construction, the Geotechnical Engineer retained to provide these services should indicate in writing that they agree with the recommendations of this report, or prepare supplemental recommendations as necessary. A final report by the “Geotechnical Engineer” should be prepared upon completion of the project.

Additional Services

We recommend that our firm be retained to review the final plans and specifications to determine if the intent of our recommendations has been implemented in those documents. We would be pleased to submit a proposal to provide these services upon request.

LIMITATIONS

Our recommendations are based upon the information provided regarding the proposed project, combined with our analysis of site conditions revealed by the field exploration and laboratory testing programs. We have used prudent engineering judgment based upon the information provided and the data generated from our study. This report has been prepared in substantial compliance with generally accepted geotechnical engineering practices that exist in the area of the project at the time the report was prepared. No warranty, either express or implied, is provided.

If the proposed construction is modified or relocated or, if it is found during construction that subsurface conditions differ from those we encountered at our exploration locations, we should be afforded the opportunity to review the new information or changed conditions to determine if our conclusions and recommendations must be modified.

We emphasize that this report is applicable only to the proposed construction and the investigated site. This report should not be utilized for construction on any other site. This report is considered valid for the proposed construction for a period of two years following the date of this report. If construction has not started within two years, we must re-evaluate the recommendations of this report and update the report, if necessary.

FIGURE 54

UNIFIED SOIL CLASSIFICATION SYSTEM (ASTM D2487)

MAJOR DIVISIONS		USCS[4]	CODE	CHARACTERISTICS
COARSE GRAINED SOILS (More than 50% of soil > no. 200 sieve size)	GRAVELS[1] (More than 50% of coarse fraction > no. 4 sieve size)	GW		Well-graded gravels or gravel - sand mixtures, trace or no fines
		GP		Poorly graded gravels or gravel - sand mixtures, trace or no fines
		GM		Silty gravels, gravel - sand - silt mixtures, containing little to some fines[2]
		GC		Clayey gravels, gravel - sand - clay mixtures, containing little to some fines[2]
	SANDS[1] (50% or more of coarse fraction < no. 4 sieve size)	SW		Well-graded sands or sand - gravel mixtures, trace or no fines
		SP		Poorly graded sands or sand - gravel mixtures, trace or no fines
		SM		Silty sands, sand - gravel - silt mixtures, containing little to some fines[2]
		SC		Clayey sands, sand - gravel - clay mixtures, containing little to some fines[2]
FINE GRAINED SOILS (50% or more of soil < no. 200 sieve size)	SILTS & CLAYS LL < 50	ML		Inorganic silts, gravely silts, and sandy silts that are non-plastic or with low plasticity
		CL		Inorganic lean clays, gravelly lean clays, sandy lean clays of low to medium plasticity[3]
		OL		Organic silts, organic lean clays, and organic silty clays
	SILTS & CLAYS LL ≥ 50	MH		Inorganic elastic silts, gravelly elastic silts, and sandy elastic silts
		CH		Inorganic fat clays, gravelly fat clays, sandy fat clays of medium to high plasticity
		OH		Organic fat clays, gravelly fat clays, sandy fat clays of medium to high plasticity
HIGHLY ORGANIC SOILS		PT		Peat
ROCK		RX		Rocks, weathered to fresh
FILL		FILL		Artificially placed fill material

OTHER SYMBOLS

= Drive Sample: 2-1/2" O.D. Modified California sampler

= Drive Sampler: no recovery

= SPT Sampler

= Initial Water Level

= Final Water Level

— — — = Estimated or gradational material change line

——— = Observed material change line

Laboratory Tests

CR = Corrosion
PI = Plasticity Index
EI = Expansion Index
UCC = Unconfined Compression Test (TSF)
TR = Triaxial Compression Test
GR = Gradational Analysis (Sieve/Hydro)
FC = Wash (Fines Content)
PP = Pocket Penetrometer Test (TSF)
PID = Photo Ionization Detector Test (PPM)
RV = Resistance ("R") Value

REF = Refusal (>50 blows in 6 inches)

GRAIN SIZE CLASSIFICATION

CLASSIFICATION	RANGE OF GRAIN SIZES	
	U.S. Standard Sieve Size	Grain Size in Millimeters
BOULDERS (b)	Above 12"	Above 300
COBBLES (c)	12" to 3"	300 to 75
GRAVEL (g) coarse fine	3" to No. 4 3" to 3/4" 3/4" to No. 4	75 to 4.75 75 to 19 19 to 4.75
SAND coarse medium fine	No. 4 to No. 200 No. 4 to No. 10 No. 10 to No. 40 No. 40 to No. 200	4.75 to 0.075 4.75 to 2.00 2.00 to 0.425 0.425 to 0.075
SILT & CLAY	Below No. 200	Below 0.075

Trace - Less than 5 percent
Few - 5 to 10 percent
Little - 15 to 25 percent
Some - 35 to 45 percent
Mostly - 50 to 100 percent

* Percents as given in ASTM D2488

NOTES:

1. Coarse grained soils containing 5% to 12% fines, use dual classification symbol (ex. SP-SM).
2. If fines classify as CL-ML (4<PI<7), use dual symbol (ex. SC-SM).
3. Silty Clays, use dual symbol (CL-ML).
4. Borderline soils with uncertain classification list both classifications (ex. CL/ML).

[illegible]

1.2 SCOPE OF SERVICES

[illegible]

and the Property Owner's representatives to [illegible]

1.3 GROUND WATER EXPLORATION PROGRAM

1.4 FAULT INVESTIGATION EXPLORATION PROGRAM

under the supervision of Cornerstone's Certified Engineering Geologist.

1.5 ENVIRONMENTAL SERVICES

[illegible]

SECTION 2: REGIONAL SETTING

[illegible]

2.1 REGIONAL GEOLOGIC SETTING

[illegible]

H[illegible]averas Faults and others (see the “Faulting” section of this report)[illegible]

2.2 LOCAL GEOLOGY

[illegible]

H[illegible]fan deposits (“Qf”)[illegible]Late Pleistocene fan deposits (“Qpf”) and Early to middle Pleistocene [illegible]fan or terrace deposits (“Qoa”).[illegible]The Qf unit is described as; “G[illegible]

[illegible] age is indicated by slight dissection and/or the development of alfisols." [illegible]

[illegible] described as "Fluvial gravel, sand, silt, and clay". [illegible] in the "Faulting" section of this report [illegible]

2.3 REGIONAL SEISMICITY

[illegible]

Table 1: Approximate Fault Distances

Fault Name	Distance (miles)	Distance (kilometers)
[illegible]	[illegible]	[illegible]
Gr[illegible]	[illegible]	[illegible]
R[illegible]	[illegible]	[illegible]
H[illegible]	[illegible]	[illegible]
Gr[illegible]	[illegible]	[illegible]
H[illegible]	[illegible]	[illegible]
Gr[illegible]	[illegible]	[illegible]

[illegible]

[illegible]

SECTION 3: SITE CONDITIONS

[illegible]

3.1 RECENT HISTORY

[illegible]

[illegible]

[illegible]

[illegible]

3.2 SURFACE DESCRIPTION/GEOMORPHOLOGY

[illegible]

3.3 GROUND WATER INVESTIGATION

[illegible]

Gr[illegible] ter[illegible] M[illegible] Gr[illegible] ter[illegible] r[illegible] M[illegible] r[illegible] M[illegible] r[illegible] M

SECTION 4: GEOLOGIC HAZARDS

4.1 FAULTING

[illegible]

[illegible]

[illegible]

[illegible] Bryant noted the [illegible]

[illegible]

[illegible] DMG [illegible] ("AP Zone") trends [illegible]

[illegible] ("SNE") [illegible]

[illegible]

rupture didn't jump the gap "releasing"

4.1.1 Proposed Sewer Line

4.2 FAULT SURFACE RUPTURE

evaluations, faults are considered "active" if they display evidence of movement within Holocene time (the last 11,000 years), and "potentially active" if they display evidence of movement within the "Mitigating Fault Surface Ruptures" section of this report

4.2.1 Previous Consultant's Studies

locate and/or "clear"

nt's investigation sites.

[1] i.e., prove lack of evidence for fault surface traces trending through the investigation area.

D r M r Myers stated: “No prominent slickensid d r r d H 2 2 r d H d M r r d r r r d r r r

the previous consultant's investigations performed within the ar

ity's reviewing geologist (Mr. James

Cornerstone's Certified Engineering Geologist. Trenches were exca

4.2.2 Current Fault Investigation

M [illegible] G [illegible] Mr [illegible]

[illegible]

[illegible]

[illegible] 2 [illegible] 5 [illegible] 2 [illegible] re Bezore's mapping indicates the surficial deposits [illegible] G [illegible] D [illegible] 2 [illegible] 5 [illegible] 2 [illegible] extended through an area where Bezore's map shows four geologic units (which include from [illegible] R [illegible]

[illegible]

4.2.3 Encountered Geologic Units in Exploratory Trenches

Unit 1–H

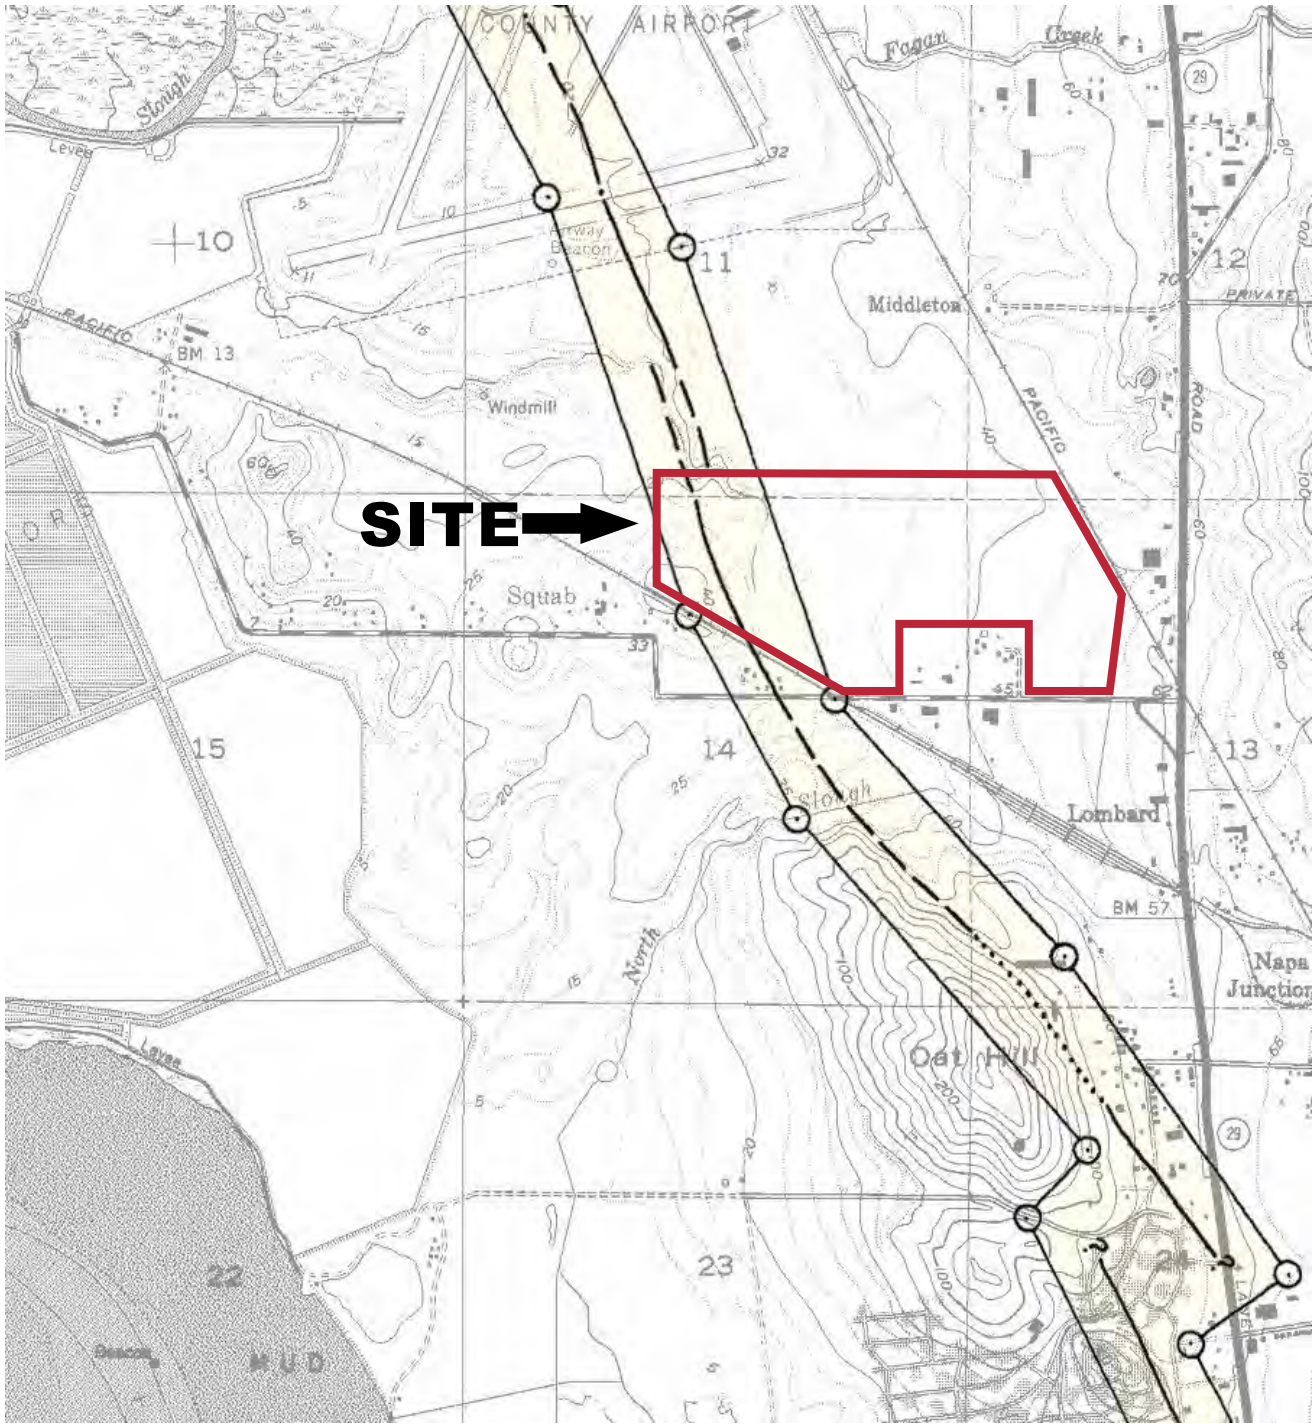

MAP EXPLANATION

Potentially Active Faults

1906 C

Faults considered to have been active during Holocene time and to have a relatively high potential for surface rupture; solid line where accurately located, long dash where approximately located, short dash where inferred, dotted where concealed; query (?) indicates additional uncertainty. Evidence of historic offset indicated by year of earthquake-associated event or C for displacement caused by creep or possible creep.

Special Studies Zone Boundaries

These are delineated as straight-line segments that connect encircled turning points so as to define special studies zone segments.

Seaward projection of zone boundary.

This Page Intentionally Left Blank

Introduction

Project PR-268-9823 was initiated in February 1998 by PRCI to provide current seismic guidelines for the design and assessment of natural gas transmission pipelines. These guidelines were refined using two rounds of review by outside technical experts in 1999 and 2000. The PRCI ad hoc steering group for the project also provided regular input regarding the scope and technical content for these guidelines. A decision was made in late 2000 to expand the scope to liquid hydrocarbon pipelines (crude oil and refined products) based upon the identical analytical treatment of seismic design and assessment of these types of pipelines.

Much of the current seismic practice can be traced to research conducted in the 1970s to develop design criteria and procedures for the Trans-Alaska oil pipeline. Many of the procedures in these guidelines have been implemented, in one form or another, by the major natural gas pipeline operators in California. The recognition of credible seismic hazards in other parts of the United States has been the primary driver for extending current practices in California to the rest of the United States. The experience in designing pipelines in seismically active regions of the United States has also provided a basis for specifying pipeline seismic design practices in other parts of the world.

The first comprehensive set of seismic guidelines for oil and gas pipeline systems was published in 1984 by the American Society of Civil Engineers[1]. These guidelines were the product of a collaborative effort among pipeline operators, consultants, and researchers. The 1984 ASCE guidelines have become accepted as a de-facto standard for seismic design within the oil and gas industry. Since their publication in 1984, considerable advancements have been made in seismic hazard definition and the understanding of pipeline response to earthquake hazards.

The present guidelines are intended to be an update of the 1984 ASCE guidelines relating to buried pipelines transporting natural gas and liquid hydrocarbons. To that end, preparation of these guidelines attempts to take full advantage of recent research findings with respect to soil loading on buried pipelines, acceptable strain-based pipeline limit states, and current analysis tools. To the extent possible, these guidelines have been stated in a concise manner with minimal discussion so as to keep the main text clear and concise. More in-depth discussions of the bases for recommendations in these guidelines are provided in a comprehensive Commentary at the end of this document. These guidelines are the product of considerable peer review by experts within the pipeline industry, key investigators at various research organizations, and consultants providing seismic design and assessment services to natural gas pipeline operators.

There continue to be advancements in understanding pipeline behavior and seismic hazard definition. It is anticipated that these guidelines will be updated as ongoing research is incorporated into actual practice.

APPENDIX E: Guideline Reviewers

1.0 GENERAL PROVISIONS

These guidelines provide recommended procedures and methods for the assessment of new and existing natural gas and liquid hydrocarbon pipelines subjected to seismic-related loading conditions. These guidelines are believed to be representative of, and consistent with, current practices for seismic hazard mitigation for these pipelines.

The specific procedures contained in these guidelines are related to determining pipeline response to predefined seismic hazards (e.g., liquefaction, fault displacement, slope instability). The process of defining these hazards is not part of the scope of these guidelines, although considerable guidance is given on typical practice and simplified approaches for estimating the potential severity of seismic hazards. The suitability of the methods described in these guidelines to define seismic hazards should be confirmed by specialists with appropriate knowledge and expertise.

1.1 Application

These guidelines are limited to onshore and offshore buried steel pipelines fabricated with full-penetration girth welds. Although the procedures of these guidelines may be extended to other applications (e.g., low-pressure distribution mains), the special considerations that apply to buried piping systems with conditions such as numerous tie-ins of distribution facilities and potential fatigue effects of large cyclic pressure fluctuations may occur during operation are not addressed.

1.2 Process

The general process for performing a design or an assessment of a buried pipeline is illustrated by the flow chart in Figure 1.1. As indicated in the flow chart, application of the procedures in these guidelines may require input from experts in specialized technical disciplines, particularly in the areas of seismology, geology, soil mechanics, and materials and welding technology. The content of these guidelines is limited to guidance regarding typical practices in these areas as they relate to the seismic assessment of buried pipelines. This information is also valuable to facilitate interaction among pipeline engineers and individuals having the requisite specialized expertise.

Most of the approaches for quantifying seismic hazards presented in these guidelines are based upon empirical relationships developed from past earthquake observations. As a result, each such approach is limited to the particular conditions characteristic of the earthquake data used to develop the underlying empirical relationship. Understanding the relative importance of these limits and rational approaches for implementing modifications for site-specific conditions is the primary reason for relying on individuals with special technical expertise.

The procedures in this document assume that the performance criteria and critical pipeline locations have been identified. The level of required seismic performance, as

defined by the annual probability of occurrence of an unacceptable condition, is a decision that needs to be made on a case-by-case basis considering public safety, environmental impacts, operational requirements, economic consequences, regulatory requirements and corporate policies. Factors to be considered when establishing performance requirements are discussed in Appendix A.

The state of knowledge in the field of pipeline response does not allow the definition of well-defined post-yield strain limits associated with some levels of pipeline performance. This is particularly true for cases where detailed knowledge of the pipeline material properties is lacking and the performance level is associated with maintaining pipeline pressure integrity. Considerable uncertainty also exists in defining seismic hazards. In these guidelines, the specification of partial safety factors associated with a rigorous reliability analysis has not been attempted. While such an approach may be desirable for specific pipelines, it is not considered practical for general application and, therefore, is not provided in these guidelines. The philosophy adopted in these guidelines is to consider conservative estimates of seismic hazards that are likely to occur. The likelihood of experiencing a seismic hazard is assumed to be equal to the acceptable probability of not achieving the performance goals for the pipeline. Pipeline response to the seismic hazard defined in this manner is assumed to utilize estimates of pipeline strength and strain capacity that are equal to or slightly more conservative than the median. The determination of what constitutes a "conservative" hazard definition and "median" pipeline strength and strain capacity is based largely upon judgment and procedures implemented in many pipeline projects and approved by various regulatory and oversight agencies over the past two decades.

These guidelines address the site-specific evaluation of a pipeline to a particular seismic ground displacement hazard. For a single pipeline, the number of site-specific conditions to be evaluated is typically based upon an assessment of conditions within 200 m to 300 m of the pipeline right-of-way. For transmission systems providing multiple feeds to large metropolitan regions, an alternate approach may be to first identify critical pipeline segments within the system. The critical segments are those portions of the system necessary to maintain life safety, avoid environmental damage, and provide reliable service. Critical segments of the pipeline may also include locations where options are not available for rapidly reconfiguring the system to isolate earthquake damage and reroute flow to maintain service. Identification of seismic hazards would then focus on the critical pipeline segments within the system. For large transmission systems in areas with numerous seismic hazards, this approach has the advantage of significantly reducing the level of effort for quantifying seismic hazards. A drawback of this approach is that damage that might occur to less critical portions of the pipeline system is not identified. Of course, when examining a single pipeline for the level of reliable service, the entire pipeline becomes a critical segment as damage anywhere along the pipeline can lead to service interruption.

1.3 Alternate Procedures

These guidelines do not preclude the use of alternate procedures for determining pipeline performance when subjected to seismic-induced load conditions. Alternative methods may be equally acceptable if based upon sound engineering and rational analysis satisfying the intent of provisions given in these guidelines. In most cases, alternative procedures are justified and feasible if they accommodate the use of site- or project-specific conditions such as those listed below:

1. Site-specific seismic hazard definition based upon more detailed knowledge of the tectonic and geologic setting in which the pipeline is operated;
2. Site-specific assessment of geotechnical conditions, e.g., potential liquefaction areas;
3. Improved characterization of pipe-soil interaction based upon field testing of in situ soil conditions or laboratory tests representative of in situ conditions; and
4. Determination of alternative pipeline limit-state criteria based upon laboratory tests representative of the full range of expected pipeline cross-sections, materials, applied load conditions and deformation states.

Alternative analysis methods must be capable of correctly capturing non-linear soil behavior, the influence of large pipeline deformations on computed pipeline strains, and post-yield or post-buckling pipeline strength characteristics.

1.4 Required Information

The analysis procedures contained in these guidelines require the following engineering information.

□□□□□□ □□□□□□□□□□□r□ □□□□□

1. Outside diameter and wall thickness of the pipe, elbows or induction bends;
2. Stress-strain relationships representative of the pipe material;
3. Toughness properties of the pipe, girth weld, seam weld, and weld heat-affected zone;
4. External coating specifications (as it relates to the pipe-soil friction interface) and thickness and type of insulation or shielding material (if any);
5. Maximum allowable operating pressure;
6. Design temperature differential between installed and operating conditions;
7. Pipeline alignment details (plan, profile, and location of fittings); and
8. For existing pipelines, reduced strain limits based upon type of girth-weld, expected material and weld defects in the girth weld and seam weld, and corrosion condition over a length of pipeline experiencing strains resulting from permanent ground displacement.

□□□2□ □□□□□r□ □□□□□

1. Depth of soil cover over a length of pipeline experiencing strains from permanent ground displacement;
2. Backfill specifications;
3. Depth to water table;
4. Water depth for offshore pipelines in the area of potential permanent ground displacement;
5. Soil strength parameters over a length of pipeline experiencing strains from permanent ground displacement and to a depth equal to the bottom of the pipe trench. The needed parameters include:
   a. Total unit weight
   b. Internal friction angle
   c. Cohesion

□□□□□□ Gr□□□d□D□□r□ □□□□□H□□rd□D□□□□□□

1. Expected amount and dominant direction of permanent ground deformation (usually defined at the ground surface);
2. Length of pipeline exposed to permanent ground deformation;
3. Variation of permanent ground deformation with depth, if any, along the length of the pipeline under consideration;
4. Variation in the direction of permanent ground deformation; and
5. Uncertainty in the location of the fault with respect to the pipeline crossing.

1.5 Acronyms

APE	annual probability of exceedance
API	American Petroleum Institute
ASCE	American Society of Civil Engineers
ASME	American Society of Mechanical Engineers
ASTM	American Society of Testing and Materials
CPT	cone penetrometer test
EPS	expanded polystyrene
HAZ	heat affected zone
NPS	nominal pipe size (NPS 12 corresponds to 12-inch and 323 mm pipe)
SMYS	specified minimum yield strength

SPT	standard penetration test
TGD	transient ground displacement
XPS	extruded polystyrene

1.6 Nomenclature

To the extent possible, the nomenclature in these guidelines matches the nomenclature in equations from various reference sources. In several cases, this leads to duplication in nomenclature. Since many terms are well established in various technical disciplines, the potential for confusion in the use of unfamiliar terms is considered a more significant drawback than duplication.

A_c	critical acceleration to trigger seismic slope instability
AD	average surface fault displacement in a vertical plane parallel to fault strike
c	cohesion representative of the soil backfill
c	apparent wave propagation velocity for estimating strains from wave propagation
c'	effective cohesive strength of slope material for landslide assessment
C_B	borehole diameter correction (assume 1.0 if unknown)
C_E	hammer energy correction ($C_E = E_{eff}/60$; assume 1.0 if unknown)
C_N	overburden correction ($\sqrt{P_a / \sigma_{ve}} \leq 2.0$)
C_Q	correction factor for assessing liquefaction using CPT test data
C_R	rod length correction ($C_R = 0.75 + 0.25(L_{rod} - 4)$; $0.75 \leq C_R \leq 1.0$)
CRR	cyclic resistance ratio for assessing liquefaction
C_S	sample liner correction (1.2 if no liner; if unknown, assume 1.0)
CSR	cyclic stress ratio for assessing liquefaction
d_s	average depth to top of seismogenic rupture zone in attenuation relationship
D	outside pipe diameter
D	depth to basement rock
D′	ovalization parameter
$D50_{15}$	mean soil particle diameter for saturated, liquefiable soils with $(N_1)_{60}$ values less than 15
D_{bore}	SPT bore hole diameter
D_F	total fault displacement

D_{FS}	component of fault displacement in a vertical plane parallel to the fault strike (quantity provided by the Wells and Coppersmith empirical fault displacement relationship)
D_{min}	minimum pipe diameter from assumed ovaling
D_r	relative density, %
D_w	depth to water table
E	random error term used in ground shaking attenuation relationships
E	modulus of elasticity
E_{eff}	percentage of hammer energy delivered to sampling rod in SPT test
f	pipe coating factor for estimating interface friction angle from internal friction angle
f_s	sleeve friction measured in a CPT conducted in accordance with ASTM D-3441
F	attenuation modification factor (0 for normal or strike-slip faulting, 1 for reverse or thrust faulting, if type of faulting unknown, use 0.5)
FFH	free face height for lateral spread displacement equation, m
FFL	distance from toe of free face, m
F_{15}	percentage of material passing through a #200 sieve from a sample of liquefiable soil with an $(N_1)_{60}$ value less than 15
F_ℓ	factor of safety against liquefaction, CRR/CSR
FC	fines content of soil as measured by percentage of a sample passing a #200 sieve
g	acceleration due to gravity
h	thickness of potential sliding soil mass
H	depth from the ground surface to the centerline of a buried pipeline
H	rupture depth, km, in attenuation relationship
H_B	depth to bottom of fault, km
H_F	horizontal component of fault displacement parallel to fault strike
H_S	depth to top of seismogenic zone, km
H_T	depth to top of fault, km
$I_{0.5}$	index parameter in CPT liquefaction assessment procedure computed for $n = 0.5$
I_1	index parameter in CPT liquefaction assessment procedure computed for $n = 1.0$

I_n	index parameter in CPT liquefaction assessment procedure computed for a specific value of n
K_c	fines content correction factor for liquefaction assessment using CPT data
K_o	coefficient of earth pressure at rest
K_σ	overburden correction factor to account for overburden stresses greater than 100 kPa
L_{anchor}	length of burial sufficient to develop yield in the pipe under relative axial soil displacement
L_D	estimated slope displacement for assessing whether or not large landslide movements are possible
L_{rod}	length of rod connected to SPT sampler, m
LSD	mean lateral spread displacement
M	earthquake moment magnitude
MD	maximum surface fault displacement in a vertical plane parallel fault strike
MSF	magnitude scaling factor for computing cyclic resistance factor
n	factor in CPT liquefaction assessment related to fines content of soil
N	SPT blow counts collected in accordance with ASTM D-1586
$(N_1)_{60}$	standard penetration resistance normalized to an overburden pressure of 1 tsf (96 kPa) and a hammer energy efficiency ratio of 60%
$(N_1)_{60FC}$	$(N_1)_{60}$ corrected for fined content of the soil
N_c	soil bearing capacity factor for vertically downward loading in clay
N_{ch}	soil bearing capacity factor for horizontal loading in clay
N_{cv}	soil bearing capacity factor for vertically upward loading in clay
N_q	soil bearing capacity factor for vertically downward loading in sand
N_{qh}	soil bearing capacity factor for horizontal loading in sand
N_{qv}	soil bearing capacity factor for vertically upward loading in sand
N_γ	soil bearing capacity factor for vertically downward loading in sand
p	internal pipeline pressure
p_y	internal pipeline pressure that produces a hoop stress equal to σ_y
P_a	reference pressure (100 kPa ≈ 14.5 psi ≈ 1 tsf)
P_{cr}	predicted collapse pressure from external pressure
P_e	elastic buckling pressure
P_{ext}	net external pressure on pipe (total external pressure - internal pressure)
P_{fr}	average annual probability of fault displacement

P_g	average annual probability associated with exceeding specified performance goal for the pipeline (e.g., 0.001 annual probability for loss of pressure integrity)
P_u	maximum lateral soil load caused by pipe lateral movement relative to the surrounding soil
P_y	axial load in a pipeline corresponding to a uniform tensile stress equal to the SMYS
PGA	peak ground acceleration at surface
q_c	tip resistance measured in a CPT conducted in accordance with ASTM D-3441
q_{c1N}	q_c normalized to an overburden pressure of P_a
$(q_{c1N})_{FC}$	q_{c1N} corrected to account for fines content
Q_d	maximum lateral soil load caused by pipe vertically downward movement relative to the surrounding soil
Q_u	maximum lateral soil load caused by pipe vertically upward movement relative to the surrounding soil
r	amount of rattle-space for culvert mitigation concept
r_d	cyclic stress reduction coefficient for assessing liquefaction using SPT data
R	earthquake source distance parameter (variously defined in equations)
R_{fp}	fault displacement reduction factor accounting for probability of fault displacement
R_S	closest distance to seismogenic rupture surface, km
*R**	effective distance from site to earthquake epicenter, km, used in lateral spread displacement equation
RLD	fault rupture length at depth
sr	fault slip rate
S	percentage of surface slope for estimating lateral spread displacement
S_{HR}	attenuation relationship surficial soil correction parameter (0 for soft rock, alluvium and firm soil, and 1 for hard rock)
S_{SR}	attenuation relationship surficial soil correction parameter (0 for hard rock, alluvium and firm soil, and 1 for soft rock)
SRL	surface rupture length, km
t	pipe wall thickness
t_u	maximum soil force on pipeline from relative axial movement
T_{15}	thickness of saturated, liquefiable, soils with $(N_1)_{60}$ values less than 15
T_F	component of fault displacement perpendicular to fault strike

V_F	component of vertical fault displacement
V_{max}	maximum ground velocity from ground shaking
W	free face ratio, expressed as percent, for estimating lateral spread displacement
W	expected down-dip fault width, km
z	depth below ground of SPT or CPT test measurement
Z_T	factor in attenuation relationship, 0 for interface event, 1 for intra-slab event in attenuation relationship
α	fault dip angle, degrees
α	coefficient for determining fines correction factor in liquefaction assessment
α	adhesion factor for estimating axial pipeline soil load
α_ε	ground strain coefficient for computing axial strains from wave propagation
α_κ	ground strain coefficient for computing bending strains from wave propagation
β	angle of regional stress azimuth for estimating fault displacement, degrees
β	coefficient for determining fines correction factor in liquefaction assessment
δ	soil interface friction angle
δ_o	initial ovalization of pipe cross-section
Δ	girth weld offset used to compute compression strain limit
Δ_d	vertical downward relative pipeline displacement caused by liquefaction
Δ_p	relative displacement between pipe and soil in lateral direction necessary to develop P_u
Δ_{qd}	relative displacement between pipe and soil in vertically downward direction necessary to develop Q_d
Δ_{qu}	relative displacement between pipe and soil in vertically upward direction necessary to develop Q_u
Δ_t	relative displacement between pipe and soil in axial direction necessary to develop T_u
Δ_u	vertical upward relative pipeline displacement caused by liquefaction
ε_{cl}	longitudinal compression strain limit for load-controlled conditions
ε_{co}	longitudinal compression strain limit for continued operation
ε_{cp}	longitudinal compression strain limit for pressure integrity
ε_{cr}	critical longitudinal compression strain
$\varepsilon_{cr\text{-}p}$	critical longitudinal compression strain for conditions with external pressure

ε_{tl}	longitudinal tension strain limit for load-controlled conditions
ε_g	ground strain related to seismic wave propagation
ε_{to}	longitudinal tension strain limit for continued operation
ε_{tp}	longitudinal tension strain limit for pressure integrity
ε_v	volumetric strain experienced by soil as the result of liquefaction
ϕ	soil internal friction angle
ϕ'	effective angle of internal friction for slope stability assessment
Φ	standard normal probability function
γ	total unit weight of soil
$\bar{\gamma}$	effective (or submerged) unit weight of soil
γ_{max}	maximum soil shear strain
γ_w	unit weight of water
κ_g	ground curvature from seismic wave propagation
λ	ratio of pore pressure to overburden stress
σ	standard deviation
σ_t	axial stress in pipeline from thermal differential
σ_y	pipe material yield stress
σ_{vo}	total soil overburden pressure
σ'_{vo}	effective soil overburden pressure
σ_{AD}	standard deviation of average fault displacement
σ_{MD}	standard deviation of maximum fault displacement
θ	slope angle

1.7 References

For clarity, references have been largely omitted from the Procedures section of these guidelines. References to the basis documents used in these guidelines are noted in the Commentary section along with a complete reference listing.

1.8 Units

Seismic design and assessment of buried pipelines invariably crosses multiple disciplines with an equal variability in the degree to which English and metric units are adopted. As many of the equations in these guidelines are adopted from other sources, the original unit system has been maintained resulting in a mix of English and metric units within these guidelines. The majority of equations in these guidelines can be used with any consistent set of units. Exceptions are noted and typically relate to empirical relationships or equations fitted to published curves to facilitate calculations using spreadsheets or other computer-based applications.

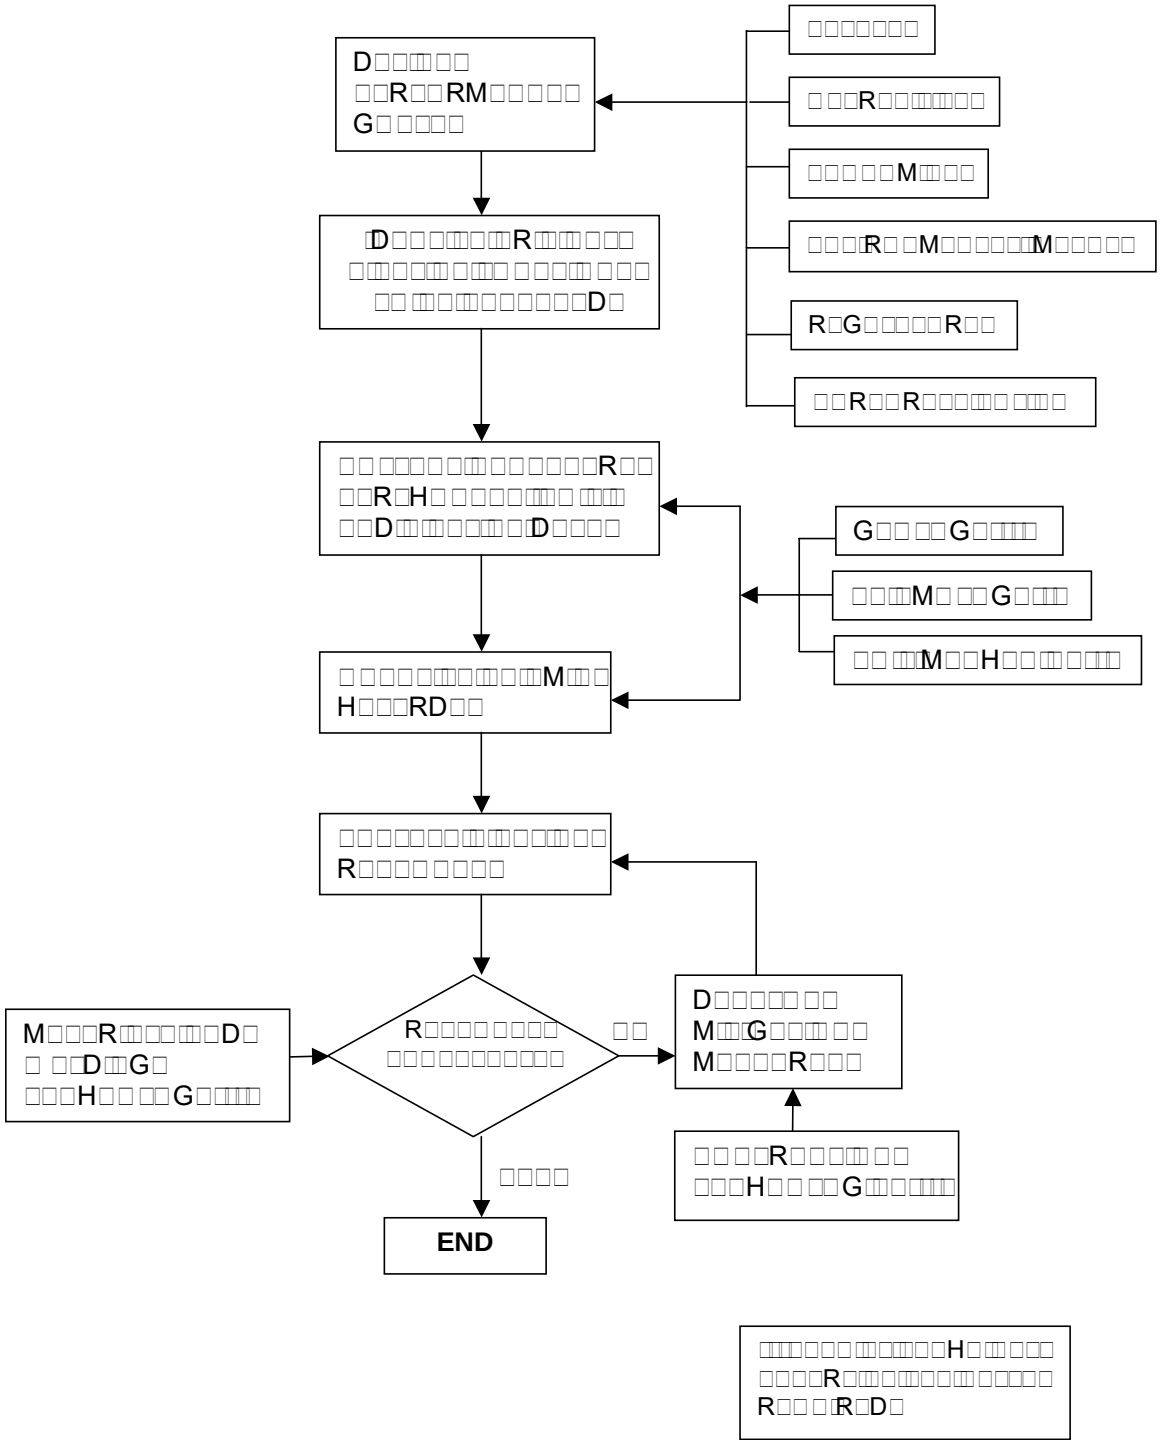

Figure 1.1: Seismic Design and Assessment Process for Assessing Seismic Hazards for Buried Natural Gas and Liquid Hydrocarbon Pipelines

2.0 QUANTIFYING SEISMIC HAZARDS

Credible seismic hazards for buried steel pressure pipelines are generally limited to those that produce permanent deformation of the ground along the pipeline alignment or large transient ground displacements that result in significant permanent deformation following an earthquake. These hazards primarily include surface faulting, liquefaction, liquefaction-induced lateral spread movement, landslides, and near-surface settlement.

Seismic wave propagation is also a consideration for buried pipelines, but it generally does not have a serious effect on buried welded steel pipelines. Transient ground deformation generally has not been a problem, except in a few special situations that are discussed in Section 2.7.

This section presents the methods and approaches commonly used to define seismic hazards for buried pipelines. Detailed coverage of the theory and development of procedures for collecting data and quantifying seismic hazards is beyond the scope of these guidelines. The information provided relies heavily on project experience and recent advances identifying and characterizing seismic hazards. It is recommended that the definition of seismic hazards be performed by individuals experienced with the methods described in this section and possessing the requisite background in seismology, geology, and soil mechanics.

The discussion of seismic hazards is organized by category and is presented in accordance with the development of parameters to define the hazard. The focus is on direct seismic hazards as opposed to potential indirect hazards from such causes as debris impact (e.g., rockfall impact) or collateral damage resulting from earthquake damage to adjacent pipelines in a common right-of-way or utility corridor.

The definition of potential seismic hazards is often developed during a separate geotechnical or geologic investigation. In lieu of such investigations, the procedures provided in this section can be followed to provide an estimate of the amount and likelihood of ground movement. These procedures are best used as a tool to determine if a pipeline is at significant risk from seismic hazards. The procedures also provide a means to identify the need for, and scope of, a more rigorous geologic or geotechnical investigation.

2.1 Surface Faulting

Surface fault rupture is an important consideration for buried pipelines, because pipelines crossing fault zones must deform longitudinally and in flexure to accommodate ground displacement. If a pipeline crosses an active fault, it is necessary to delineate its location, orientation, width of fault rupture zone, and the amount and direction of potential fault displacement.

The term “active fault” implies a judgment on the part of a geologist that the fault could experience surface rupture within the time frame established by the performance goals for

the pipeline (e.g., an average annual probability of exceedance less than $1x10^{-3}$). Generally, a fault is considered active if it can be demonstrated to have displaced the ground surface during the Holocene epoch (i.e., within the past 11,000 years).

For some faults, a characteristic earthquake and associated recurrence interval may have been established through field studies and historical seismicity. For such cases, the expected fault displacement may be estimated as the cumulative slip between characteristic earthquakes (i.e., the slip rate per year times the recurrence interval). Otherwise, it is more meaningful to rely on empirical relationships such as those described in Section 2.1.1.

Some faults experience aseismic creep in addition to surface rupture produced by an earthquake. For pipeline design, the total fault movement, including creep, is important since both lead to deformation of the pipeline. The effects of creep need to be considered separately because the slow rate of displacement is consistent with drained soil loading conditions while fault displacement occurs rapidly under undrained conditions. This impacts the determination of soil loads on the pipeline as discussed in Section 4.

It is recommended that fault displacement estimates for the design or assessment of pipeline response be approached as a three-stage process:

1. Estimate the expected fault displacement of an active fault;

2. Adjust the estimate of expected fault displacement based upon the consequences of pipeline damage and pipeline performance objectives to obtain the design fault displacement; and

3. Convert the design fault displacement to orthogonal displacement components relative to the fault (i.e., vertical component, horizontal component parallel to the fault strike, and horizontal displacement perpendicular to the fault strike).

2.1.2.1 Empirical Methods Based on Fault Rupture Length

The most common method for estimating surface fault displacements relies on observations of fault displacements during past earthquakes. Wells and Coppersmith (1994) developed a series of empirical relationships that relate moment magnitude, *M*, surface rupture length, subsurface rupture length, down-dip rupture width, rupture area, and maximum and average displacement per event. The most commonly used Wells and Coppersmith relationships that are used when other information is lacking provide maximum and average fault displacements (MD and AD) as function of fault surface rupture length or moment magnitude.

Estimating MD and AD as a function of surface rupture length is generally preferred because the determination of fault displacement is based directly upon the geologic attributes of the fault. Using earthquake moment magnitude to estimate MD and AD is more indirect because it is based upon a two-stage correlation of moment magnitude to fault parameters (typically either surface rupture length or seismogenic rupture area) and

fault displacement to magnitude. However, relating fault displacement to earthquake magnitude is preferable for situations where earthquake magnitude has been previously established by other geologic investigations.

For estimating fault displacement (MD or AD) as a function of surface rupture length (SRL), the following regression formulae from Wells and Coppersmith (1994) apply:

$$\log(MD) = -1.38 + 1.02 \cdot \log(SRL) \qquad [\log(\sigma_{MD}) = 0.41] \qquad (2\text{-}1a)$$

$$\log(AD) = -1.43 + 0.88 \cdot \log(SRL) \qquad [\log(\sigma_{AD}) = 0.31] \qquad (2\text{-}1b)$$

where:

- AD = Average surface fault displacement, m
- MD = Maximum surface fault displacement, m
- SRL = Surface rupture length, km. The surface rupture length is the maximum length of the fault segment crossing the pipeline that, by reasonable and qualified judgment, can be expected to rupture during an earthquake.
- σ_{MD} = Standard deviation of maximum displacement regression
- σ_{AD} = Standard deviation of average displacement regression

The data sets for the two regression equations listed above include displacement data for all types of slip, i.e., strike-slip, normal and reverse faulting. The displacements estimated by the relationships of Wells and Coppersmith (1994) is the vector sum of the horizontal and vertical slip components along the fault strike. The implications of this definition on determining three-dimensional components of fault displacement are discussed further in Section 2.1.2.

Wells and Coppersmith (1994) also provide relationships for estimating maximum and average fault displacements as a function of moment magnitude (M). These relationships are provided below.

$$\log(MD) = -5.46 + 0.82 \cdot M \qquad [\log(\sigma_{MD}) = 0.42] \qquad (2\text{-}2a)$$

$$\log(AD) = -4.80 + 0.69 \cdot M \qquad [\log(\sigma_{AD}) = 0.36] \qquad (2\text{-}2b)$$

2.1.2.2 Orthogonal Components of Fault Displacement

As a final step in defining fault displacement, the design fault displacement determined in Section 2.1.2 must be transformed into orthogonal components of fault displacement. This is necessary only if fault displacement is estimated using equations (2-1) or (2-2), since these expressions only provide the net displacement in a vertical plane perpendicular to the strike of the fault. The transformation to orthogonal displacement components relative to the fault strike is illustrated in Figure 2.1. The following equations provide the transformation:

Total fault displacement, D_F:

$$D_F = \frac{D_{FS}}{\sqrt{\sin^2\alpha + \left(\cos^2\alpha\right)\left(\cos^2\beta\right)}} \quad \text{(2-3a)}$$

Vertical displacement, V_F:

$$V_F = D_F \sin\alpha \quad \text{(2-3b)}$$

Horizontal displacement parallel to the fault strike, H_F:

$$H_F = D_F \cos\alpha \cos\beta \quad \text{(2-3c)}$$

Transverse horizontal displacement perpendicular to the fault strike, T_F:

$$T_F = D_F \cos\alpha \sin\beta \quad \text{(2-3d)}$$

Apparent dip angle, α:

$$\tan\alpha = \tan\delta \sin\beta \quad \text{(2-3e)}$$

where:

D_{FS} = fault displacement in a vertical plane parallel to the fault strike

δ = fault dip angle corresponding to "average" dip angle inherent in equations (2-1) and (2-2) (see Commentary). Lacking other information, the dip angle can be taken as 75° for strike slip faults, 60° for normal slip faults, and 45° for reverse or thrust faults.

β = horizontal angle between fault strike and regional stress azimuth. For faults that are predominantly strike slip, this angle is 0°, and for faults that are predominantly reverse or normal faults, this angle will be 90°. Other faults will have some combination of strike and reverse/normal slip, with an angle, β, between 0° and 90°.

2 D D

Determination of a design fault displacement is based upon estimates of expected average and maximum fault displacements described in Section 2.1.1. Design fault displacements are determined based upon consideration of the performance requirements for the pipeline and the consequences for loss of pipeline pressure integrity. Two modifications are recommended for determining design fault displacements, one to account for the consequences of loss of pipeline pressure integrity and another to account for faults with a low likelihood of occurrence relative to the pipeline performance criteria.

2.1.3.1 Accounting for Consequences of Loss of Pressure Integrity

It is preferable that design fault displacements be based upon the uncertainty in fault displacement and site-specific consideration of the potential risk (likelihood of a particular type of damage and consequences) associated with earthquake-related pipeline damage. In lieu of such considerations, the following design factors are recommended to account for the consequences of loss of pipeline pressure integrity and the expected recurrence interval for fault displacement:

1. Consider the mean maximum fault displacement for natural gas pipelines and flammable or explosive petroleum products pipelines in Location Class 4 areas (ASME B31.8).
2. Consider two-thirds of the mean maximum fault displacement for natural gas pipelines and flammable or explosive petroleum products pipelines in Location Class 3 areas (ASME B31.8).
3. Consider two-thirds of the mean maximum fault displacement for petroleum products pipelines located in environmentally sensitive areas.
4. Other natural gas or liquid hydrocarbon pipelines in other areas than above should be designed for the mean average fault displacement.

Prior to use, the above guidelines should be carefully reviewed and evaluated by the pipeline owner or its representatives for consistency with project objectives and regulatory requirements.

2.1.3.2 Accounting for Expected Occurrence of Fault Displacement

The time frame for defining a fault to be active is typically an order of magnitude greater than the typical performance goals for a pipeline (e.g., 11,000 years for the Holocene epoch versus a pipeline performance goal of a 1,000-year average return period for experiencing loss of pressure integrity). To account for this, it is recommended that the expected fault displacements be reduced when the estimated likelihood of fault displacement is less than the acceptable probability of not achieving pipeline performance goals. A simple correction factor based upon the ratio of the probability of fault displacement and pipeline performance goal is recommended as defined by equation (2-4):

$$R_{fp} = \frac{P_{fr}}{2P_g} \tag{2-4}$$

where:

R_{fp} = reduction factor accounting for probability of fault displacement

P_{fr} = average annual probability of fault displacement

P_g = average annual probability associated specified performance goal (e.g., $1x10^{-3}$ mean annual probability for loss of pressure integrity)

If fault displacements are determined by other means than equation (2-1) or (2-2), appropriate steps should be taken to determine orthogonal components in the vertical, horizontal and transverse directions.

2.2 Peak Ground Acceleration

Estimates of peak ground acceleration (PGA) are required for quantifying permanent ground displacement hazards related to liquefaction, lateral spread movement, and landslide movement. Ground shaking is estimated using empirical attenuation equations representing the decrease in ground motion with increasing distance from the fault rupture plane. There are many attenuation relationships available, and many are developed to represent specific types of earthquakes and specific geologic and tectonic environments.

Peak ground acceleration can be obtained from the results of probabilistic hazard analyses or deterministically based upon a postulated earthquake on a known fault. Probabilistic hazard analyses typically form the basis for building code earthquake hazard maps. The details of how probabilistic hazard analyses are performed is a specialized field and is beyond the scope of these guidelines. However, a summary of the general procedures is provided in Appendix C to familiarize the reader with the general concepts.

Deterministic estimates of peak ground acceleration are relatively straightforward to apply provided an attenuation relationship is selected that is appropriate for the earthquake mechanism and tectonic and geologic characteristics of the area.

A deterministic approach to estimating peak ground acceleration is required for assessing other hazards related to liquefaction and some approaches for assessing slope instability. Where probabilistic hazard analyses are available, it may be possible to infer a magnitude and acceleration value from the details of the calculation of the probabilistic hazard. Selecting a suitable combination of magnitude and acceleration from a probabilistic hazard estimate should be performed by individuals familiar with the generation of the probabilistic hazard and the seismicity of the region.

The two relationships presented in Sections 2.2.1 and 2.2.2 are provided to illustrate some of the general characteristics and differences in attenuation relationships. These relationships were developed for near-source earthquakes (western United States) and subduction zone (Cascadia region) earthquakes. It is ***strongly*** recommended that users seek out specific attenuation relationships applicable for the region in which the pipeline is located.

Both attenuation relationships contain an error term, E, that represents a factor that can be used in conjunction with a standard normal probability table to estimate the probability of exceeding the mean of ln(PGA) represented by the equation. For example, for a mean estimate, the standard normal probability, $\Phi(x)$ is 0.5 (50%) and the value of x is 0. If the probability of exceedance is desired to be less than 16%, $\Phi(x)$ is 0.84, x is 1.0 and the value of ln(PGA) is increased by E which is equivalent to multiplying the PGA by e^E.

Other percentile levels may be established by selecting values of $\Phi(x)$ consistent with the percentile associated with the desired probability of non-exceedance.

The attenuation relationships also illustrate the potential variability in the amount and types of information needed for their application. This is particularly true for definitions of source-to-site distance. The near source earthquake relationship requires more descriptive information on the fault plane and the portions of the fault capable of generating earthquake ground motions (the seismogenic part of the fault) in order to compute this distance. There is also a difference in the number of parameters used to characterize the site.

2.2 [illegible]

$$\ln(PGA) = -3.512 + 0.904M - 1.328\ln\sqrt{R_S^2 + \left[0.149e^{0.647M}\right]^2} + \left[1.125 - 0.112\ln(R_S) - 0.0957M\right]F + \left[0.440 - 0.171\ln(R_S)\right]S_{SR} + \left[0.405 - 0.222\ln(R_S)\right]S_{HR} + f_A(D) + E\Phi^{-1}(x) \quad (2\text{-}5)$$

where:

PGA = peak ground acceleration, g

M = moment magnitude

F = 0 for normal and strike-slip faulting

= 1 for reverse or thrust faulting

= 0.5 if type of faulting unknown

R_S = closest distance to seismogenic rupture, km

= $\sqrt{R^2 + d_S^2}$

R = horizontal projection of closest site to seismogenic rupture distance, km

d_S = average depth to the top of the seismogenic rupture zone, km

= $\frac{1}{2}\left[H_B + H_T + W\sin(\alpha)\right] \geq H_S$

H_B = depth to bottom of fault, km

H_S = depth to top of seismogenic part of the crust, km

H_T depth to top of fault, km

W = expected down-dip fault width, km

= $10^{-1.01+0.32M}$

α = fault dip angle

$f_A(D)$ = 0 if D ≥ 1 km, otherwise

= $\left\{\left[0.405 - 0.22\ln(R_S)\right] - \left[0.440 - 0.171\ln(R_S)\right]S_{SR}\right\}(1-D)(1-S_{SR})$

D = depth to basement rock, km

E = random error term = $0.889 - 0.691M$

Φ = standard normal probability function

x = cumulative probability of actual *PGA* being less than or equal to *PGA* from the attenuation relationship

S_{SR} = 0 for hard rock, alluvium, and firm soil

= 1 for soft rock

S_{HR} = 1 for hard rock

= 0 for soft rock, alluvium, and firm soil

For generic rock sites, S_{SR} = 1, S_{HR} = 0, and D = 1 km.

For generic soil sites, S_{SR} = 0, S_{HR} = 0, and D = 5 km.

2.2.2 [illegible]

$$\ln(PGA) = 0.2418 + 1.414M - 2.2.552\ln\left(R + 1.7818e^{0.554M}\right) + 0.00607H + 0.3846Z_T + E\Phi^{-1}(x) \quad \text{for rock} \qquad (2\text{-}6a)$$

$$\ln(PGA) = -0.6687 + 1.438M - 2.329\ln\left(R + 1.097e^{0.617M}\right) + 0.00648H + 0.3643Z_T + E\Phi^{-1}(x) \quad \text{for soil} \qquad (2\text{-}6b)$$

where:

H = rupture depth, km

R = closest distance to fault rupture, km

Z_T = 0 for interface event, 1 for intra-slab event

E = $1.45 - 0.1M$ but not greater than 0.65

2.3 Liquefaction

Liquefaction hazards to pipelines include flotation, sinking, and general ground settlement from dissipation of excess pore water pressure. Pipeline flotation or sinking requires the pipe to be located below the ground water table within a zone of liquefiable soil. Ground settlement occurs when a liquefiable soil layer beneath a layer of competent

soil densifies. If the pipeline is located in the layer of competent soil near the surface, it will be subjected to displacement associated with subsidence of the ground.

Quantification of liquefaction hazards requires site-specific information on the subsurface soil properties and peak ground acceleration. Soils information can most commonly be obtained through subsurface investigations using the standard penetration test (SPT) and cone penetration test (CPT). These investigations should be performed by personnel experienced in the interpretation of soil boring logs and liquefaction assessment. Parameters used in the assessment of liquefaction potential are summarized in Table 2.1.

Liquefaction also may cause lateral spreads or flow slides. These hazards are discussed in Sections 2.4 and 2.5.

2□□□□□ □□□□□□

$$r_d = \frac{1-0.4113\sqrt{z}+0.04052z+0.001753z^{1.5}}{1-0.4177\sqrt{z}+0.05729z-0.006205z^{1.5}+0.001210z^2}$$

z = depth of interest (z must be in meters for computing r_d)

σ_{vo} = total overburden soil pressure at test location = γz

σ'_{vo} = effective soil overburden pressure = $\gamma z - \gamma_w(z - D_w)$

D_w = depth to water table

γ = unit weight of soil

γ_w = unit weight of water

2.3.1.1 Assessment of Liquefaction Using SPT Data

The *CRR* is computed as follows:

for $x \geq 3$,

$$CRR = \frac{MSF \cdot K_\sigma (4.8(10)^{-2} - 4.721(10)^{-3}x + 6.136(10)^{-4}x^2 - 1.673(10)^{-5}x^3)}{1-1.248(10)^{-1}x + 9.578(10)^{-3}x^2 - 3.285(10)^{-4}x^3 + 3.714(10)^{-6}x^4} \quad (2\text{-}8a)$$

for $x < 3$,

$$CRR = 0.05 \cdot MSF \cdot K_\sigma \quad (2\text{-}8b)$$

where:

x = $(N_1)_{60FC}$, the normalized SPT data corrected for fines content

MSF = magnitude scaling factor for approximately a 32% chance of liquefaction

= $10^{3.74}/M^{4.33}$

K_σ = overburden pressure correction factor for $\sigma'_{vo} > P_a$

= 1 for $\sigma'_{vo} \leq P_a$

$= 0.514 + \frac{0.897}{\left(\sigma'_{vo}/P_a\right)} - \frac{0.411}{\left(\sigma'_{vo}/P_a\right)^2}$ for $P_a < \sigma'_{vo} < 10P_a$

= 0.6 for $\sigma'_{vo} \geq 10P_a$

P_a = reference pressure (100 kPa ´ 14.5 psi ´ 1 tsf)

The expression for *CRR* is based largely upon past earthquake observations for earthquakes with magnitudes of approximately 7.5. This expression is depicted graphically in Figure 2.2 as a function of $(N_1)_{60FC}$ for *MSF* and K_σ equal to 1.0.

Two steps are used to correct the measured SPT data. First, the measured SPT value, *N*, is corrected using equation (2-9) to account for specific test procedures and normalized to an effective overburden pressure equal to P_a. The second correction accounts for the greater liquefaction resistance of soils with larger quantities of fine-grained material. In this case, the fines content, *FC*, is determined as the percentage of material passing through a #200 sieve (0.074 mm opening). The normalized SPT value, $(N_1)_{60}$, is computed as follows:

$$\left(N_1\right)_{60} = N \cdot C_N \cdot C_E \cdot C_B \cdot C_R \cdot C_S \qquad (2\text{-}9)$$

where:

$\left(N_1\right)_{60}$ = SPT value normalized to P_a and 60% hammer energy efficiency

N = measured SPT

C_N = overburden correction = $\sqrt{P_a / \sigma'_{vo}} \le 2.0$

C_E = hammer energy correction

= $E_{eff}/60$ (assume 1.0 if unknown)

E_{eff} = hammer energy efficiency, percentage

C_B = borehole diameter correction (assume 1.0 if unknown)

C_R = rod length correction

= $0.75 + 0.04(L_{rod} - 4)$ $\qquad (0.75 \le C_R \le 1.0)$

L_{rod} = length of rod in SPT test (L_{rod} must be in meters for computing C_R)

C_S = sample liner correction (1.2 if no liner; assume 1.0 if unknown)

The following expression corrects the $(N_1)_{60}$ value for the effect of fines content, *FC*:

$$(N_1)_{60FC} = \alpha + \beta (N_1)_{60} \qquad (2\text{-}10)$$

where α and β are defined as follows:

Fines Content, *FC*	α	β
5% or less	0	1.0
Greater than 5% to less than 35%	$e^{1.76-\frac{190}{FC^2}}$	$0.99+\frac{FC^{1.5}}{1000}$
35% or greater	5	1.2

2.3.1.2 Assessment of Liquefaction Using CPT Data

Data collected from cone penetrometer tests (CPT) need to be corrected for normalized test conditions and the fines content of the soil. Since no samples are collected in CPTs, the fines content correction relies on inferred conditions from the ratio of measured tip bearing, q_c, and friction value, f_s. The equation for computing *CRR* from CPT data is given below:

For $(q_{c1N})_{FC} < 50$

$$CRR = \left[\frac{0.833 \cdot (q_{c1N})_{FC}}{1000} + 0.05\right] MSF \tag{2-11a}$$

For $50 \le (q_{c1N})_{FC} < 160$

$$CRR = \left[93\left(\frac{(q_{c1N})_{FC}}{1000}\right)^3 + 0.08\right] MSF \tag{2-11b}$$

where:

$(q_{c1N})_{FC}$ = tip resistance normalized to P_a and corrected for fines content

The measured tip resistance is normalized to an effective overburden pressure equal to P_a and corrected for fines content. These corrections are dependent upon the value of I_n, a parameter related to the granular nature of the soil.

$$I_n = \sqrt{(3.47 - \log Q_n)^2 + (1.22 + \log F)^2} \tag{2-12}$$

$$Q_n = \frac{(q_c - \sigma_{vo})}{100}\left(\frac{100}{\sigma'_{vo}}\right)^n \tag{2-13}$$

$$F = \left[\frac{f_s}{q_c - \sigma_{vo}}\right] 100\% \tag{2-14}$$

where:

q_c = CPT tip bearing pressure

f_s = CPT side friction pressure

The value of *n* used in equations (2-13) and (2-14) is, in turn, dependent upon the resulting value of I_n. Determination of *n* requires computing I_n for values of n equal to 0.5 ($I_{0.5}$) and 0.1 (I_1). The value of n is then determined as follows:

n = 1.0 if I_1 greater than 2.6 (clayey)

n = 0.5 if I_1 and $I_{0.5}$ less than 2.6 (granular)

n = 0.7 if I_1 less than 2.6 and $I_{0.5}$ greater than 2.6 (silty)

The normalized CPT tip resistance, $(q_{c1N})_{FC}$, is then computed as shown below:

$$(q_{c1N})_{FC} = K_c C_Q \left(\frac{q_c}{P_a} \right) \tag{2-15}$$

where:

K_c = 1.0 for $I_n \leq 1.64$

= $-17.88 + 33.75 I_n - 21.63 I_n^2 + 5.581 I_n^3 - 0.403 I_n^4$ for $I_n > 1.64$

$C_Q = \left(\frac{P_a}{\sigma'_{vo}} \right)^n$

2□□2□ D□□□□□□□□ □□□□□□□□□□□□□d□□ □□□R□□□□□□□□ □□□□□□□□□

Pipeline flotation is a displacement-controlled phenomenon for onshore pipelines. The amount of displacement is limited by the distance between the bottom of the pipe and the water table or the depth of soil cover plus about 1/3 the pipe diameter for cases where the water table is at the ground surface. This is an upper limit assuming that the liquefied state is maintained for a long time. Otherwise, the displacement is further limited by the velocity at which the pipeline moves through the liquefied material and the "drag" as the pipe moves through the liquefied soil. Offshore pipelines or pipelines crossing bodies of water will tend to float if they are not at least neutrally buoyant with respect to the unit weight of the liquefied soil.

Pipelines that are negatively buoyant with respect to the unit weight of the liquefied soil are subject to sinking if they are located within a liquefiable soil deposit. The amount of sinking is limited by the distance between the bottom of the pipe and the depth to non-liquefiable soil. This is an upper limit assuming that the liquefied state is maintained for a long time. Otherwise, the displacement is further limited by the velocity at which the pipeline moves through the liquefied material similar to flotation.

The length of pipeline exposed to liquefaction is dependent upon the subsurface extent of liquefiable soil and the alignment of the pipeline through the zone of liquefaction. Determining the length of exposed pipeline can be made through subsurface investigations at regular intervals along the pipeline. Alternatively, the extent of

exposure may be estimated based upon obvious changes in surface geology (e.g., a transition from deltaic deposits to rock or glacial till).

2 [illegible] D [illegible] R [illegible] d [illegible] d [illegible]

Liquefaction-induced settlements are credible hazards to pipelines located within liquefiable layers of soil. For the more typical onshore case where the pipeline is located above the water table, liquefaction-induced settlement is a credible hazard if the liquefiable layer is close enough to the surface to produce settlement in near-surface soil layers. One means to determine this possibility is to compare the thickness of the liquefied layer and the depth to the liquefied layer. The screening curves in Figure 2.3 are based upon observations of where surface settlements have been sufficient to cause structural damage in past earthquakes. Since buildings are generally more susceptible to damage from settlement, the use of Figure 2.3 can be used as a conservative screening guideline for buried pipelines.

The amount of liquefaction-induced settlement can be estimated for each sandy soil layer using Figure 2.4. For each soil layer, the amount of volumetric strain is taken from Figure 2.4 based upon the factor of safety against liquefaction and the relative density of the soil or the corresponding corrected blowcount, $(N_1)_{60FC}$. The total amount of settlement is estimated by multiplying the volumetric strain by the thickness of each soil layer below the invert of the pipeline. Utilization of Figure 2.4 is made by computing the factor of safety against liquefaction, F_ℓ, as given by the ratio of *CRR* to *CSR*.

2.4 Lateral Spread Movement

The most appropriate method to estimate lateral spread movement is to rely on computer-based approaches that account for the actual strength properties of the liquefied soil. These programs typically are limited to two-dimensional representations of the soil. They have the advantage of being able to quantify variation in the magnitude and direction of soil displacements. Examples of two commonly used programs are SOILSTRESS and DESRA, both developed at the University of British Columbia. In addition, there are many research-oriented programs and special purpose programs used within the geotechnical community.

In lieu of computer analyses, an estimate of lateral spread movement can be obtained using empirical relationships developed from lateral spread and soil data collected in past earthquakes in the United States and Japan (Youd et al., 2002), as shown below.

For sloping ground conditions (Figure 2.5):

$$\begin{aligned} Log(LSD) = & -16.213 + 1.532M - 1.406LogR^* \\ & - 0.012R + 0.338LogS + 0.540LogT_{15} \\ & + 3.413Log(100 - F_{15}) - 0.795Log(D50_{15} + 0.1) \end{aligned} \quad \text{(2-16a)}$$

For free face conditions (Figure 2.6):

$$\begin{aligned} Log(LSD) = & -16.713 + 1.532M - 1.406LogR^{*} \\ & -0.012R + 0.592LogW + 0.540LogT_{15} \\ & +3.413Log(100 - F_{15}) - 0.795Log(D50_{15} + 0.1) \end{aligned} \quad \text{(2-16b)}$$

where:

LSD = horizontal lateral spread movement (m)

M = earthquake moment magnitude $[6.0 < M < 8.0]$

R = epicentral distance, km

R^{*} = $R + R_o$

R_o = $10^{0.89M - 5.64}$

S = ground slope (%) $[0.1 < S < 6.0]$

W = free face ratio (%) = $100(FFH/FFL)$ $[1 < W < 20]$

FFH = height of free face

FFL = distance from base of free face

T_{15} = thickness (m) of saturated cohesionless soils with $(N_1)_{60} < 15$ $[1 < T_{15} < 15]$

$(N_1)_{60}$ = standard penetration blowcount normalized to P_a and 60% driving efficiency

F_{15} = average fines content (%) in T_{15} $[0 < F_{15} < 50]$

$D50_{15}$ = average median particle size (mm) in T_{15} $[0 < D50_{15} < 50]$

The limits associated with the above variables represent the range of values in the Bartlett and Youd data set. The simplified approach may result in significant error if site-specific conditions deviate significantly from these limits. Note that the range of $(N_1)_{60}$ is limited to less than 15. Available data indicate that lateral spread displacement does not occur in sediments with $(N_1)_{60}$ greater than 15.

Variation in ground displacement away from a free face can be estimated by computing the displacement using the free face equation (2-16b) with increasing values of FFL (i.e., decreasing free face ratio, W). This is relatively straightforward because there is only one term dependent upon the free face ratio.

The foregoing methods for estimating permanent ground movement relate to maximum displacements in a lateral spread. For the evaluation of pipeline behavior, it is necessary to estimate a transverse distribution of the pattern of ground deformation within the soil mass that moves across or along a buried pipeline. Considerations for defining the pattern of ground displacement are provided in Section 4.5.

2.5 Landslides

Strong ground shaking during earthquakes may trigger landslides in a variety of geologic and topographic settings as depicted in Figure 2.7. The potential threat to pipeline performance is a function of the following:

1. The amount of landslide displacement;
2. The depth of the landslide relative to the depth of the pipeline;
3. The type of ground displacement associated with the landslide movement (i.e., block-type (coherent) movement or disrupted movement); and
4. The direction of landslide movement relative to the pipeline.

An approximate estimate of the magnitude of triggered landslides can be made using the approach sometimes adopted for regional identification of the extent of landslide hazards. The basis of the recommended approach is the sliding block analysis approach developed by Newmark (1965). The approach is applicable to both disruptive and coherent slides. Disruptive slides typically are shallow and are broken during movement into small blocks, rock fragments, or soil particles. Coherent slides typically are deeper seated movements of intact blocks of soil or rock. For both types of slides, a hazard to the pipeline exists only if the pipeline is above the interface of the potential slide zone.

The recommended approach for identifying the potential for triggered landslides requires an estimate of the critical acceleration, A_c, that will trigger down-slope displacement for the type of slide and material. The critical acceleration can be computed using the following equation developed for the assumption of a constant slope and material strength:

$$A_c = \frac{c'}{\gamma \cdot h} + (1-\lambda)\tan\phi' \cos\theta - \sin\theta \qquad (2\text{-}17)$$

where:

h = thickness of the potential landslide

θ = slope steepness angle

c' = effective cohesion of the slope material under dynamic conditions

ϕ' = effective friction angle of the slope material under dynamic conditions

λ = ratio of the pore pressure to overburden stress = $\gamma_w(h - D_w)/\gamma h \leq 0.6$

D_w = depth to water table

γ = unit weight of soil

γ_w = unit weight of water

Equation (2-17) can be used to plot values of A_c as a function of slope angle for various values of c' , ϕ' , h, γ, and D_w.

An example of a plot of A_c versus slope angle is illustrated in Figure 2.8. The curves in Figure 2.8 are based upon common slope material properties listed in Table 2.2 and assume h = 10 ft and γ = 100 pcf. The two groups of curves in Figure 2.8 correspond to completely saturated conditions (i.e., the water table is at the ground surface) or unsaturated conditions (i.e. the water table depth is greater than h).

The computation of slope displacement generally requires the double integration of earthquake ground accelerations larger than the critical acceleration, A_c, that cause the forces driving slope displacement to exceed the resisting forces. This approach implies that one or more ground motion time histories representative of the site under consideration are available. As a simpler alternative, empirical relationships that envelop the displacements computed for a range of time histories are available for estimating slope displacement as a function of peak ground acceleration, *PGA*.

The amount of landslide movement, L_D, can be estimated using the following bounding relationships.

For very firm ground or rock conditions

$$L_D = 1.7 \cdot PGA \cdot (1 - \frac{A_c}{PGA}) \cdot \left(\frac{PGA}{A_c} \right)^2 \qquad \text{(2-17a)}$$

For soil conditions

$$L_D = 3.0 \cdot PGA \cdot (1 - \frac{A_c}{PGA}) \cdot \left(\frac{PGA}{A_c} \right)^2 \qquad L_D \text{ in inches for Group C} \qquad \text{(2-17b)}$$

where:

A_c = critical acceleration (% of gravity) from Figure 2.8

Triggered landslides should be considered possible if L_D is greater than 1 inch (25 mm) for disruptive landslides or 4 inches (100 mm) for coherent landslides. If the possibility of a triggered landslide exists, site-specific investigations should be performed to quantify the magnitude, extent, and likelihood of landslide movements.

The evaluation of pipeline behavior in landslide areas requires the definition of a displacement pattern for the displaced soil mass as shown in Section 4.5.

2.6 Seismic Wave Propagation

Body waves, including compression waves and shear waves, propagate radially from the source of earthquake energy release (hypocenter) into the surrounding rock and soil medium. Compression waves cause axial compression and tension strains in the ground in a radial direction away from the hypocenter. Shear waves cause shear strains in the ground perpendicular to these radial lines. When the compression waves and shear waves are reflected by interaction with the ground surface, surface waves (Love waves and Rayleigh waves) are generated. Except at very large distances from the epicenter, the magnitudes of surface waves are much less than body waves.

A pipeline buried in soil that is subject to the passage of these ground waves will incur longitudinal and bending strains as it conforms to the associated ground strains. In most cases, these strains are relatively small, and welded pipelines typically do not incur damage. Propagating seismic waves also give rise to hoop membrane strains and shearing strains in buried pipelines, but these strains are even smaller and may be neglected.

A relatively simple method based upon an approach developed by Newmark (1965) can be used to obtain an upper-bound estimate of ground strain due to a propagating seismic wave with a constant shape (sine wave). The maximum ground strain, ε_g, is given by:

$$\varepsilon_g = \frac{V_{\max}}{\alpha_\varepsilon c} \tag{2-19}$$

where:

V_{max} = Maximum horizontal ground velocity in the direction of wave propagation

c = Apparent propagation speed of seismic wave (i.e., the component of wave speed parallel to the pipeline under consideration)

α_ε = Ground strain coefficient corresponding to the most critical angle of incidence and type of seismic wave

= 1.0 for compression and Rayleigh waves (ASCE, 1984)

= 2.0 for shear waves (ASCE, 1984)

The apparent propagation velocity is the inverse of the "slowness," a term used in seismology. The slowness is a function of the source-to-site geometry and the wave propagation velocity along the entire path of propagation. Tables of earthquake wave travel times will exist wherever detailed earthquake location work has been performed. An apparent propagation velocity of 2 km/sec can generally be taken as a lower bound estimate to provide a maximum estimate of ground strain.

If there is no slippage of the pipeline relative to the surrounding soil, then the maximum axial strain in the pipeline is equal to maximum ground strain. The ground strain coefficient corrects this ground strain for the effects of pipe orientation relative to the

particular wave motions. If slippage occurs, then pipeline longitudinal strains will be less than the ground strain; hence the assumption that pipeline strain is equal to ground strain is a conservative upper-bound.

The development of the maximum ground strain in the pipeline is dependent upon whether or not there is sufficient pipeline length and a sufficiently long wave length over which to establish equilibrium without longitudinal slipping of the pipeline within the soil. For very soft soils, the assumption of no slipping may lead to a significant overestimate of the strains that can be transferred from the ground to the pipeline.

The maximum ground curvature, κ_g, is the second derivative of the transverse displacement and is given by:

$$\kappa_g = \frac{PGA}{\alpha_\kappa c^2} \tag{2-20}$$

where:

α_κ = Ground curvature coefficient corresponding to the most critical angle of incidence and type of seismic wave

= 1.6 for compression waves (ASCE, 1984)

= 1.0 for shear and Rayleigh waves (ASCE, 1984)

The bending strains calculated by equation (2-20) are of small magnitude. Therefore, as a rule, the effect of curvature associated with seismic wave propagation is neglected.

For buried piping or pipeline segments with significant bends, the strain associated with seismic wave propagation will be influenced by both the virtual anchorage caused by the bend and the local flexibility of the pipe bend. An analysis approach that accounts for these conditions for buried pipelines subjected to thermal strain is provided in Appendix VII of ASME/ANSI B31.1. The same analysis approach may be suitable for determining the effects of seismic wave propagation by equating the seismic strains to thermal strains.

2.7 Transient Ground Deformation

Large transient ground deformations, associated with shear failure of weak soils or liquefaction of subsurface soil layers, have been identified as a potential cause of pipeline damage in recent earthquakes. Two conditions for transient ground deformation (TGD) have been identified based upon investigations following the 1989 Loma Prieta and 1994 Northridge earthquakes in California.

One condition susceptible to TGD is a site close to the earthquake epicenter (typically within 20 km) that is characterized by a narrow valley filled with weak soil overlying much stronger soil deposits and bounded by steep side walls. Such valleys are susceptible to direct lateral loading as the surrounding side walls experience long period displacement pulses associated with the directivity of earthquake rupture (i.e., earthquake

"fling"). During the earthquake, the motions imparted to the soft soil by the surrounding side walls of the valley are sufficient to generate shear failure in the weak soil. This shear failure decouples the soft soil from the motions of the surrounding side walls and can lead to large transient relative motions at the interface between the weak soil and the stronger soil deposits at depth.

The second condition susceptible to TGD is a site experiencing liquefaction in soil confined by non-liquefiable material. In this case, liquefaction acts to decouple the soil response from that of the surrounding non-liquefiable material leading to the potential for large transient relative motions at the boundaries between liquefied and competent soils.

There are no established procedures for identifying and quantifying TGD. Techniques that have been used to identify TGD are limited to studies to identify the cause of failures in older pipelines not typical of current construction practices (i.e., girth welds with severe defects, pipelines with large-angle mitre joints, or pipelines with corrosion defects). The few past studies performed have used detailed subsurface information and analyses incorporating actual earthquake time histories from nearby ground motion recording stations.

Table 2.1 Information Required for Performing Liquefaction Assessment

	Information Required	Notation
SPT Assessment	SPT blow counts collected in accordance with ASTM D-1586	N
	SPT bore hole diameter	D_{bore}
	Length of rod connected to SPT sampler	L_{rod}
	Percentage of hammer energy delivered to sampling rod in SPT	E_{eff}
	Fines content of soil as measured by % of a sample passing a #200 sieve	FC
CPT Assessment	CPT tip resistance in accordance with ASTM D-3441	q_c
	CPT sleeve friction in accordance with ASTM D-3441	f_s
SPT and CPT Assessment	Depth to water table at the time of the SPT or CPT	D_w
	Earthquake moment magnitude	M
	Peak ground acceleration at surface	PGA
	Unit weight of soil	γ
	Depth below ground of test measurement	z

3.0 PIPELINE PERFORMANCE CRITERIA

The most common type of loads generated on a buried pipeline by seismic hazards is generated by ground movement relative to the pipeline. The pipeline sees no further soil load once it has deformed sufficiently to match the ground movement. This type of loading is commonly referred to as displacement-controlled. Guidance is provided for two performance goals associated with displacement-controlled conditions, maintaining strains to a level that normal operations can continue and maintaining the pressure integrity of the pipeline.

Pipelines buried with minimal soil cover or in relatively weak soils and subjected to high axial loads as a result of ground movement may experience upheaval buckling. While initial pipeline response is displacement controlled, upheaval of the pipeline can lead to some strain relaxation and a related concentration of compression strain in the vicinity of pipeline upheaval. The amount of strain concentration that can occur is limited by the axial soil restraint on the portion of the pipeline that remains buried. This type of behavior is referred to as displacement-limited. Development of significant pipeline compression sufficient to cause upheaval buckling should be avoided by proper orientation of the pipeline relative to the direction of ground movement. Where upheaval buckling can not be avoided, the potential for pipe strains to concentrate needs to be investigated. Such an investigations will typically consider the bending moment capacity of the pipeline, the length of pipeline that might release strain into the portion pipeline undergoing upheaval displacement, and changes in soil restraint as a function of pipeline upheaval displacement. Full treatment of upheaval buckling is beyond the scope of these guidelines.

In some cases, a seismic hazard results in a condition where loads act continuously on the pipeline. This type of loading is commonly referred to as load-controlled. Pipeline strains for load-controlled loading conditions must remain below the strain associated with reduced load carrying capacity of the pipeline. Guidance is also provided for strain limits associated with load-controlled conditions.

All of the strain limit equations in this section are based upon recommendations from previous testing programs. In nearly all cases, strains were measured over a length of pipe, often referred to as the gauge length, equal to 0.5 to 2.0 pipe diameters. For tests that produced wrinkles or buckling in the pipe wall, the gauge length encompassed the wrinkle and buckle. Therefore, the strain limits in this section are applicable to analyses that can resolve global pipe response over a distance of one pipe diameter or less. More refined analytical representation of the pipe (e.g., use of shell elements) will provide information on the strains at a location of local pipe wall distortion. Alternate strain criteria need to be developed to relate pipe performance to these localized strains.

Pipeline performance criteria are defined in terms of allowable longitudinal compression and tension strains for onshore pipelines. The strain criteria assume that an analysis of pipeline response will be performed using finite element techniques and bilinear representation of soil loads as described in Section 4.0. The criteria defined in this section are not applicable to analyses based upon approximations of pipeline response

carried out using hand calculations that cannot resolve pipeline strains within a length of approximately one diameter.

3.1 New Pipelines and Pipelines Compatible with Modern Construction Practices

The strain limits provided in this section are applicable to pipelines that meet the following conditions:

1. Pipe material and fabrication equivalent to that specified in API 5L
2. Joint connections using full-penetration butt welds in portions of the pipeline expected to experience stresses near or above yield (e.g., no belled-end welded joints, slip joints, lap-welded joints, sleeves)
3. Weld quality consistent with current welding procedures (e.g., API 1104)
4. Weld strength matching or exceeding the expected actual pipe strength
5. Pipe, weld, and heat-affected zone toughness:

   (a) Average Charpy energy greater than 40 J (30 ft-lb), or

   (b) Average CTOD toughness greater than 0.20 mm.

6. Ratio of yield strength to tensile strength (Y/T) less than 0.92

Strain limits for computed longitudinal compression and tension strains (hereafter referred to as simply compression and tension strains) are provided for three conditions:

1. Strains resulting from imposed ground displacements with the goal of maintaining pressure integrity of the pipeline with a high likelihood of repairs to the pipeline following the earthquake;
2. Strains resulting from imposed ground displacements with the goal of maintaining normal operation of the pipeline with a low likelihood of repairs to the pipeline following the earthquake; and
3. Strains resulting from load conditions in which the displacement of the pipeline is not limited by ground displacement.

[illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible]

The performance goal, “maintain pressure integrity,” accepts significant ovalization and possible initiation of wrinkle formation in the body of the pipe. With this performance goal, post-earthquake response should include provisions to reduce operating pressure and perform site investigations to identify indications that permanent ground deformation has occurred. Replacement of the damaged portion of the pipeline may be necessary to resume normal operations.

Longitudinal Compression Strain Limit

$$\varepsilon_{cp} = 1.76\frac{t}{D} \quad \leq \quad \text{the longitudinal tension strain limit} \tag{3-1}$$

Longitudinal Tension Strain Limit

$$\varepsilon_{tp} = 0.02 \text{ to } 0.04 \quad \text{(see Commentary)} \tag{3-2}$$

□□□□2□ □□r□r□ □□□□□G□□□□M□□□□□□□□ r□ □□□□ □□r□□□□□□

The performance goal, “maintain normal operability,” provides a high level of confidence of no significant pipeline damage. The expression in equation (3-1) is valid for diameter to pipe wall thickness ratios of 100 or less and provides a term to account for an assumed level of pipe ovaling.

Longitudinal Compression Strain Limit

Recommended relationships for allowable longitudinal compression strains for continued operation are provided for two types of typical pipeline stress-strain curves: (1) those exhibiting typical rounded shapes at yield and (2) those that exhibit a distinct yield plateau.

Rounded Stress-Strain Curve with Plain Pipe Imperfection

$$\varepsilon_{co} = 0.437\left(\frac{t}{D}\right)^{1.72}\left[1-0.892\left(\frac{p}{p_y}\right)\right]^{-1}\left(\frac{E}{\sigma_y}\right)^{0.70}\left(1.09-\left(\frac{\Delta}{t}\right)^{0.086}\right) \tag{3-3a}$$

Rounded Stress-Strain Curve with Pipe End Offset at Girth Weld

$$\varepsilon_{co} = 0.056\left(\frac{t}{D}\right)^{1.59}\left[1-0.868\left(\frac{p}{p_y}\right)\right]^{-1}\left(\frac{E}{\sigma_y}\right)^{0.85}\left(1.27-\left(\frac{imp}{t}\right)^{0.15}\right) \tag{3-3b}$$

Distinct Yield Plateau with Plain Pipe Imperfection

$$\varepsilon_{co} = 1.06\left(\frac{t}{D}\right)^{2}\left[1-0.50\left(\frac{p}{p_y}\right)\right]^{-1}\left(\frac{E}{\sigma_y}\right)^{0.70}\left(1.10-\left(\frac{\Delta}{t}\right)^{0.09}\right) \tag{3-3c}$$

Rounded Stress-Strain Curve with Pipe End Offset at Girth Weld

$$\varepsilon_{co} = 0.404\left(\frac{t}{D}\right)^2\left[1-0.906\left(\frac{p}{p_y}\right)\right]^{-1}\left(\frac{E}{\sigma_y}\right)^{0.80}\left(1.12-\left(\frac{imp}{t}\right)^{0.15}\right) \quad \text{(3-3d)}$$

where:

t = pipe wall thickness

D = pipe outside diameter

p = internal pressure

p_y = internal pressure to produce hoop stress equal to yield stress

σ_y = yield stress

E = modulus of elasticity of pipe material

imp = blister-type initial imperfection expressed as a percentage of wall thickness

Δ = offset between pipe joints at girth weld

Longitudinal Tension Strain Limit

$\varepsilon_{to} = 0.01$ to 0.02 (see Commentary) (3-4)

□□□□□□ □□□d□□ □□□r□□□d□□ □□d□□□□□

The primary earthquake hazards to buried pipelines result in load conditions that are controlled by the ability of the pipeline to conform to the displacement of the ground (displacement-controlled). It is possible that situations can arise in which the loading on the pipeline is not related to permanent ground displacement. For these conditions, pipeline strength is of primary importance. The strain criteria for load-controlled conditions are based upon preventing formation of local wrinkling of the pipe wall and preventing large post-yield tension strains.

Longitudinal Compression Strain Limit:

$$\varepsilon_{cl} = 0.75\varepsilon_{co} \geq 2.42\left(\frac{t}{D}\right)^{1.59} \quad \text{(3-5)}$$

Longitudinal Tension Strain Limit:

$$\varepsilon_{tl} = 0.005 \quad \text{(3-6)}$$

Note that the maximum tension strain limit is equal to the nominal yield strain for pipe materials consistent with API 5L. Given this, the use of the pipe yield stress as a controlling acceptance criterion is also acceptable. If compression strain limits are determined to be less than 0.005, the allowable compression stress limit should be established based upon the stress-strain properties of the pipe material.

3.2 Considerations for Offshore Pipelines

Offshore pipelines that are simply laid on the sea floor with minimum embedment, so as not to be constrained by burial in the soil, can generally accommodate significant levels of deformation without damage. Sections of a pipeline that are trenched into the sea floor will exhibit seismic response characteristics similar to those of onshore pipelines. Both trenched and untrenched pipelines are vulnerable to hazards similar to onshore pipelines including submarine landslides and liquefaction-induced lateral spreads, flow failures, and debris flows. Like onshore debris flows, submarine debris flows can move very quickly and may present a significant load-controlled design condition for an offshore pipeline. In addition, offshore pipelines may be subjected to turbidity currents related to submarine ground failure.

Analysis of offshore pipelines proceeds in the same manner as for onshore pipelines. Assessment of computed pipeline strains needs to address the effects of external pressure to reduce the available compression bending strain. For offshore pipelines, the compression longitudinal bending strain limit is given by equation (3-7):

$$\varepsilon_{cr-p} = \varepsilon_{cr}\left(g - \frac{P_{ext}}{P_{cr}}\right) \tag{3-7}$$

where:

$\varepsilon_{cr\text{-}p}$ = longitudinal compression strain for condition with external pressure

ε_{cr} = limiting compression strain from Section 3.1

P_{ext} = net external pressure = total external pressure – internal pressure

$P_{cr} = \dfrac{P_e \cdot P_y}{\sqrt{P_e^2 + P_y^2}}$ = predicted collapse pressure

$P_e = 2.2 \cdot E\left(\dfrac{t}{D}\right)^3$ = elastic buckling pressure with Poisson's ratio = 0.3

$P_y = \dfrac{2 \cdot \sigma_y \cdot t}{D}$ = pressure to produce cross-section yielding

$$g = \frac{\sqrt{1+\frac{P_y}{P_e}}}{\sqrt{\frac{1}{\left(\sqrt{1+\frac{\delta_o^2 D^2}{t^2}}-\frac{\delta_o D}{t}\right)^2}+\left(\frac{P_y}{P_e}\right)^2}} \le 1$$

δ_o = initial ovalization

3.3 Pipelines Not Compatible with Current Construction Practices

Older pipelines may not conform to the attributes listed in Section 3.1, particularly with respect to pipe toughness and absence of corrosion or weld defects. These conditions may be accounted for in the assessment by appropriate reduction of the allowable strain limits in Sections 3.1.1 through 3.1.3.

Some older pipelines were constructed with a variety of girth weld details with oxyacetylene or arc welding techniques that predated modern day controls on filler material and flux composition and power supply, and lacked good quality control. Bell-and-spigot or bell-bell-chill-ring details are examples of older girth weld details. In addition, older pipelines may have been fabricated in manner that would not be permitted under current codes with such details as mitre bends, wrinkle bends, hot and cold field bends to accommodate changes in alignment. The strain capacity of these types of joints and conditions is highly variable and generally low compared to modern construction. Strain acceptance criteria for these types of pipelines need to be developed on a case-by-case basis. Acceptable approaches for establishing strain criteria include full-scale testing, finite element shell analyses, wide-plate testing, and fracture mechanics evaluations.

More rigorous approaches to establishing allowable strains based upon pipeline inspections and fracture mechanics principles are strongly encouraged. Selecting methods appropriate for specific pipe and load conditions is an area of active research that is not sufficiently developed for incorporation into general seismic guidelines.

4.0 PIPELINE ANALYSIS PROCEDURES

Finite element analysis of pipeline response to imposed ground movements is the preferred means to assess pipeline response using the provisions of these guidelines, particularly considering the advent of high-speed, desktop computers and the proliferation of relatively inexpensive, user-friendly finite element analysis software. The recommended approach is to represent the pipeline with pipe or beam elements and represent the soil loading on the pipeline with discrete spring elements. This approach is illustrated in Figure 4.1.

There are no restrictions on the analysis software that can be used as long as it is capable of capturing the non-linear effects of non-linear soil springs, user-defined stress-strain curves for the pipe material, and large changes in pipeline geometry. The definition of soil springs assumes that the spring forces always act in the axial, horizontal, and vertical directions relative to the pipeline. To maintain this condition for situations where ground and pipeline movements are large, the analysis model should be capable of defining the soil spring displacements relative to the local pipeline coordinate system. The analysis should be capable of accounting for the effects of internal pressure because the hoop stress from internal pressure reduces the longitudinal stress at which the material will yield. It is also very beneficial if the analysis software has the capability to provide computed strains at multiple locations around the circumference of the elements used to represent the pipeline.

4.1 Pipe Element Definition

The pipe element length in regions where the pipe strain is expected to exceed the yield strain (typically at abrupt transitions in ground displacement or locations with abrupt changes in soil restraint such as elbows) generally should not exceed one pipe diameter. Multiple straight or curved pipeline elements can be used to model elbows and bends in the pipeline alignment. The maximum length of pipeline elements used to model elbows should not represent more than a 15° angular change (e.g., at least 6 elements to model a 90° elbow). It is preferable to use multiple curved pipe elements at bends and elbows if they are available. In most cases, the differences in results between using curved pipe elements versus many straight pipe elements are not significant.

4.2 Pipe Stress-Strain Definition

Nonlinear material representation in analysis software is typically based upon a definition of a uniaxial engineering stress-strain curve that is converted to a true stress-strain curve within the software application. Users typically have several options to choose from regarding the modeling of plasticity. For the analysis methodology adopted in these guidelines, bilinear or multilinear isotropic hardening rules based upon a von Mises yield criterion are adequate. Alternate approaches to modeling plastic behavior can also be adopted provided they have a sound basis in engineering mechanics.

4.3 Soil Spring Definition

Soil loading on the pipeline is represented by discrete nonlinear springs as illustrated in Figure 4.1. The maximum soil spring forces and associated relative displacements necessary to develop these forces are computed using the equations given in the sections below.

Soil properties representative of the backfill should be used to compute axial soil spring forces. Other soil spring forces should generally be based upon the native soil properties. Backfill soil properties are appropriate for computing horizontal and upward vertical soil spring forces only when it can be demonstrated that the extent of pipeline movement relative to the surrounding backfill soil is not influenced by the soils outside the pipe trench.

Although tests have indicated that the maximum soil force on the pipeline decreases at large relative displacements, these guidelines are based upon the assumption that the soil force is constant once it reaches the maximum value. The dimension for the maximum soil spring force is force per unit length of pipeline. The equations below are based upon buried pipelines in uniform soil conditions.

For deeply buried pipelines with variable soil properties between the ground surface and the pipeline depth, the equations below may not be representative of the true soil loading conditions. Guidance on how to proceed with variable soil conditions is provided in the Commentary.

Horizontal soil loads on offshore pipelines resting on the sea floor increase more gradually with displacement due to the formation of a mound of soil in front of the pipeline. Determination of the soil spring characteristics for this condition requires special treatment by experienced practitioners and is not covered in these guidelines.

The expressions for maximum soil spring force are based upon laboratory and field experimental investigations on pipeline response, as well as general geotechnical approaches for related structures such as piles, embedded anchor plates, and strip footings. Several of the equations have been derived to fit published curves to facilitate their use in spreadsheets or other computer-based applications.

□□□□□□ □□r□□□□□ □□□□□ □□□□ □r□□□□

The equations for determining upward vertical soil spring forces are based upon small-scale laboratory tests and theoretical models. For this reason, the applicability of the equations is limited to relatively shallow burial depths, as expressed as the ratio of the depth to pipe centerline to the pipe diameter (*H/D*). Conditions in which the *H/D* ratio is greater than the limit provided below require case-specific geotechnical guidance on the magnitude of soil spring force and the relative displacement necessary to develop this force.

$$Q_u = N_{cv}cD + N_{qv}\gamma HD \qquad (4\text{-}3)$$

where:

N_{cv} = vertical uplift factor for clay (0 for $c = 0$)

N_{qv} = vertical uplift factor for sand (0 for $\phi = 0°$)

$N_{cv} = 2\left(\frac{H}{D}\right) \le 10$ applicable for $\left(\frac{H}{D}\right) \le 10$

$N_{qv} = \tan(\phi)\left(\frac{\phi}{44}\right)\left(\frac{H}{D}\right) \le N_q$ (see Section 4.3.4 for definition of N_q)

Δ_{qu} = displacement at Q_u

Δ_{qd} = displacement at Q_d

= $0.1D$ for granular soils

= $0.2D$ for cohesive soils

4.4 Extent of Pipeline Model

The length of pipeline modeled outside of the zone of applied ground movement is dependent upon the specific pipeline alignment. The length of pipeline needs to be sufficient to assure that small elastic deformations outside the area of high pipeline strains do not significantly change the magnitude of the highest computed longitudinal strains. An estimate of the extent of the model for which the pipe can be considered anchored to the soil, L_{anchor}, can be computed using the following formula:

$$L_{anchor} = \frac{\pi D t \sigma_y}{T_u} \quad (4\text{-}5)$$

The length L_{anchor} is the distance necessary for the axial soil force, T_u, to generate axial yield in the pipeline. Termination of pipelines within a zone of ground deformation should force the pipeline to move with the ground. For example, analysis of straight pipelines crossing faults will have one end of the pipeline model fixed at a distance L_{anchor} from the fault and the other end displaced an amount consistent with the fault movement.

For pipelines that do not have a straight alignment outside of the zone of ground movement (e.g., side bends, over bends, sag bends), a virtual anchor location may exist at a distance considerably less than that estimated by equation (4-6). This actual point at which the pipeline is anchored needs to be considered on a case-by-case basis. If the location of anchorage is not readily apparent, the modeling can include the actual pipe configuration for a pipe length equal to L_{anchor}. Any anchorage provided by the pipe configuration (e.g., bends, elbows, changes in soil cover) will then be captured in the analysis.

4.5 Representation of Applied Ground Movement

Ground movements representative of the displacement patterns and amplitudes for lateral spreads or landslides are applied to the base of the soil spring elements. The ground deformations should be specified based upon estimates of relative ground movement at the depth of the pipeline. Ideally, the expected pattern of ground displacement should be determined on the basis of geotechnical field investigations, but such may not be feasible in all cases considering the spatial extent of pipelines and the potential for numerous hazard areas.

It is always conservative to assume that the ground displacement occurs abruptly. Abrupt ground displacements have been observed at surface faults, as well as the head of landslides and lateral spreads. In some locations, it may be possible to infer future ground displacement patterns from past earthquake displacements. For locations with little earthquake experience to aid in the determination of ground deformation pattern, an abrupt offset cannot be ruled out without the assistance of a specialist in geology or geotechnical engineering.

4.6 Sensitivity Analyses

The selection of material properties, soil strengths, and ground movement patterns is an inherently uncertain process. Generally, additional analyses should be performed to provide information on the sensitivity of the computed strain levels to changes in input parameters when the level of conservatism associated with the input parameters is not well understood. This information can be used to better define the “best estimate” of pipe response and provide information that can be used to assess the level of confidence in the expected pipeline performance. The range of variation to be used in these sensitivity analyses generally can be estimated in conjunction with the selection of baseline parameters and any geotechnical investigations of soil properties and ground deformations. Unless other information is available to determine the amount of variation,

the following are suggestions for examining the sensitivity of the results obtained by analysis:

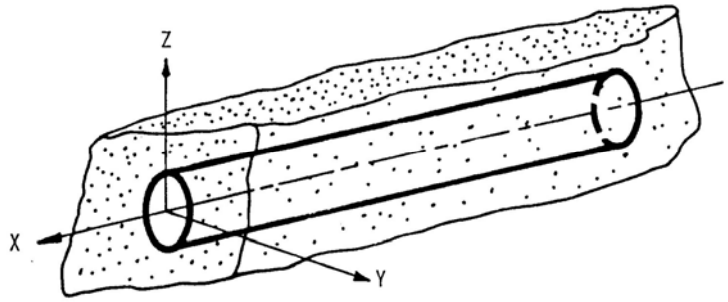
1. Upper-bound estimates of pipe material strength (as opposed to specified minimum values);

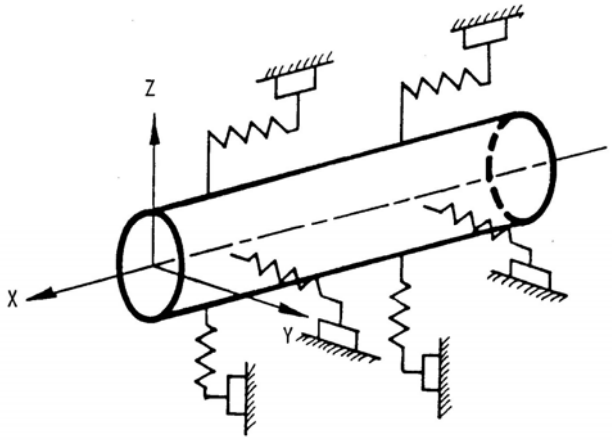
2. Variation in soil strength to capture the reasonable range of upper-bound and lower-bound ranges;

3. Increased applied ground displacement (this can normally be done at the time of the analysis); and

4. Modifications in the ground displacement transitions at boundaries with zones of potential ground movement.

The above variations typically result in a range of acceptable ground displacements or a range of strains for a particular ground displacement value. If a balanced range of parameters is selected, the "best estimate" of pipe response can typically be estimated from the resulting range in pipeline response determined from the variation in input parameters.





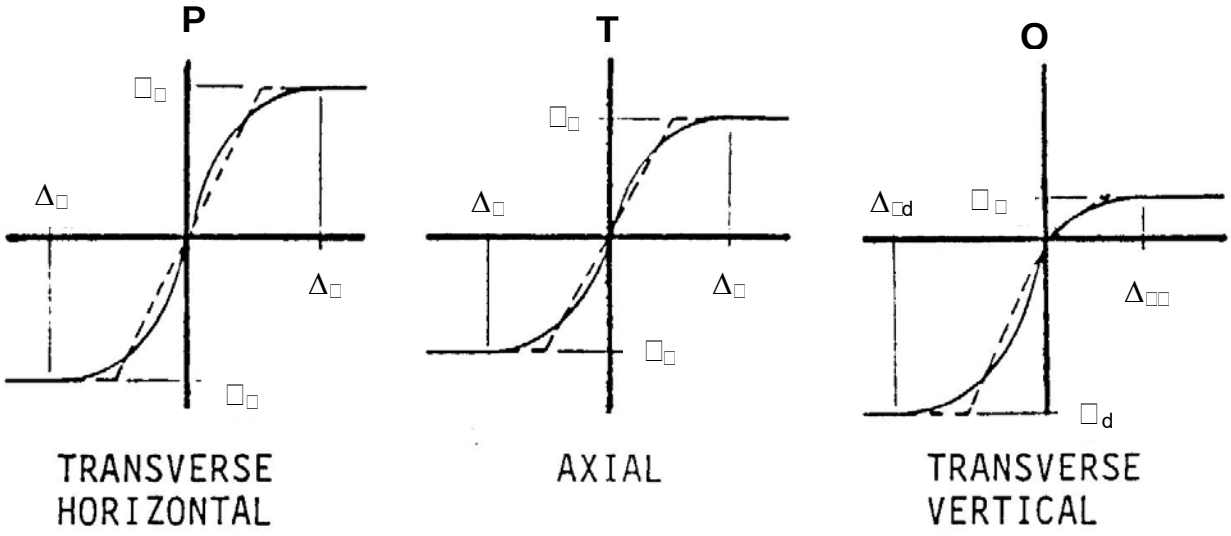


Figure 4.1 Pipeline Modeling Approach

5.0 MITIGATION OPTIONS

There are several options to improve post-earthquake conditions if the pipeline response is found to exceed the acceptance criteria defined in 3.0. Selection of a particular approach is dependent upon considerations that vary with pipeline location, expected failure mode, potential for collateral damage, risk acceptance philosophy, and estimated mitigation costs. Mitigation options fall into one of four categories: (1) relocate the pipeline to avoid the hazard, (2) modify/design the pipe construction to reduce the soil loads on the pipeline, (3) modify the pipeline configuration to increase its ability to resist ground displacement, and (4) modify post-earthquake response procedures to address the consequences of pipeline damage. Relocation to avoid the hazard requires no further explanation. The following discussion focuses on pipeline installation changes and operational measures to improve pipeline performance.

5.1 Modifying Pipeline Loading Conditions

Soil loads on buried pipelines can be reduced in several ways. The most common approach is to minimize the strength of the soils surrounding the pipeline or the frictional characteristics of the pipeline. The alignment of the pipeline can also be modified to change the orientation and distribution of soil loads with respect to the pipeline. Finally, provisions can be made to isolate the pipeline from relative soil movement. Potential options for implementing changes to modify the soil loading on buried pipelines are summarized below. Many of the options have limited applicability because of restrictions related to right-of-way access, the need to avoid existing subsurface structures and utilities, or the compaction requirements associated with various types of land use. Urban environments are particularly restrictive with respect to the feasibility of mitigation options to improve pipeline response.

5 R d M r r

The capacity of a buried pipeline to withstand ground displacements can be improved by minimizing the longitudinal, lateral, and uplift soil resistance to pipe movements.

5.1.1.1 Loose Granular Backfill

A practical means for achieving minimum soil restraint is to bury the pipeline in a shallow trench filled with a loose granular backfill. As depicted in Figure 5.1, the trench walls should be sloped at an angle of about 30° to 45° for horizontal ground displacement components and about 60° for vertical ground displacement components. This trench geometry will allow the soil to fail within the backfill material rather than in the higher strength, undisturbed soil outside the trench.

For typical pipeline trench conditions, loose granular backfills (sand or gravel) will offer less resistance to pipe movement than compacted cohesive backfill materials (clay or silty clay). A granular material with an angle of internal friction of 35° or less is

recommended. To satisfy an angle of internal friction of 35° or less, the backfill material should be a well-graded granular material with 100 percent of the aggregate less than one inch (25 mm) in diameter. The material should be obtained from a natural well-graded fluvial deposit; crushed rock is not acceptable. The backfill should be moderately compacted to a relative density, D_r, of 66 percent or less if achievable.

The assumption of any particular soil condition and the development of spring restraint properties must be consistent with field conditions. In particular, for horizontal relative ground displacement, the logarithmic spiral failure surface (depicted in Figure 5.2) must be enveloped by the limits of the excavated pipe trench that is backfilled with the selected material. Similarly, for vertical relative ground displacements, the upward breakout must occur within the designated backfill. If these trench excavation and backfill requirements are not satisfied, soil parameters applicable to the hybrid situation of in situ soils and trench backfill must be considered in the development of soil restraints for the pipeline, and these restraint properties are typically much higher than for loose granular backfill.

5.1.1.2 Locating Pipeline at or Above Grade

Lateral soil loads can be greatly reduced by placing the pipeline on the ground surface or on aboveground supports. Typcially this is done by attaching sliding shoes to the pipeline that bear on structural steel members tied to the ground or mounted in an aboveground configuration (e.g., aboveground segments of the Trans-Alaska pipeline). Teflon, or other low-friction materials, can be incorporated into the construrction of the sliding shoes to improve the ability of the pipeline to accommodate ground displacement by sliding laterally. Several options for such a modification are shown in Figure 5.3. Where soil cover is required to protect the pipeline from third-party damage, an earthen berm can be used in lieu of burial. Locating pipelines above ground is rarely a practical solution outside of controlled access areas or very remote regions. However, in some cases, it is feasible to construct a sliding support configuration at the bottom of an open trench. The top of the open trench is will generally be covered (e.g., steel grating) to protect the pipeline from vandalism and reduce the impacts on surface activities.

5.1.1.3 Low-Friction Coating or Protective Wrapping

Axial soil friction loads can be further reduced over what is achieved by loose backfill by the use of smooth, hard, low-friction coatings. Larger reductions in axial soil friction can be obtained by creating a preferred slip surface other than the pipe-soil interface. One means of achieving this is to use two separate layers of geosynthetic wrapping as shown in Figure 5.4a. This type of installation forces axial slip to occur at the interface between the two layers of geotextile fabric and can reduce the interface friction angle used to calculate maximum axial soil spring force to less than 10°. In practice, the reduction in axial soil friction force obtained from a double geotextile fabric wrapping should be verified by field tests under soil and backfill conditions that replicate the actual installation. The effects of aging on the low friction interface should also be evaluated.

5.1.1.4 Geosynthetic Lining of Sloped Trench Walls

Additional reduction in horizontal soil load over what can be achieved using loose granular backfill in conjunction with sloped trench walls (see 5.1.1.1) is possible by lining the walls of the trapezoidal trench with two layers of geosynthetic fabric. The two layers of geosynthetic fabric create a low-friction failure surface in lieu of the logarithmic spiral failure surface that would be developed in the backfill material. The load necessary to overcome the friction between the two layers of geosynthetic fabric is much less than that required to develop a shear failure in the backfill soil.

5.1.1.5 Replacing Soil with Geofoam

Geofoam materials offer a means to reduce axial, lateral, and upward vertical soil loads. Geofoam is a rigid cellular plastic foam of either expanded polystyrene (XPS) or extruded polystyrene (EPS). Geofoam has been used extensively in northern Europe for subgrade insulation in regions susceptible to frost heave. Another usage of geofoam in Europe and the U.S. is as low-density fill for construction over weak soils. One common application is to use geofoam as fill for bridge approaches and abutments. Geofoam varies in weight from about 160 N/m^3 (1 lb/ft^3) to 470 N/m^3 (3 lb/ft^3). Compressive strength of XPS is generally less than EPS although the compressive strength of both increases with density. The typical range of compressive strengths is 140 kPa to 240 kPa (20 psi to 35 psi) for EPS and 200 kPa to 500 kPa (30 psi to 75 psi) for XPS.

Replacing soil above the pipeline with geofoam reduces axial friction force by effectively reducing overburden stresses acting normal to the pipeline. Care must be taken to maintain a proper balance between limiting pipeline restraint for ground movement, yet providing sufficient restraint to prevent upheaval buckling of straight pipe and excessive bending stress at pipe bends due to operating load conditions.

Lateral loads/restraints on buried pipelines also can be reduced by using geofoam to replace much of the backfill soil as shown in Figure 5.4b. This load reduction is achieved due to two factors. First, the boundary between soil and geofoam forms a failure surface that is weaker than that corresponding to the logarithmic spiral failure surface depicted in Figure 5.2. Second, the weight of material displaced along the soil-geofoam boundary is much less. The shearing force can be reduced even further by placing loose sand between the geofoam and the native soil or through the use of dual layers of geosynthetic fabric at the interface.

The use of geofoam has some advantages in urban settings because the compressive strength of the geofoam is sufficient to handle light traffic loads. Potential significant drawback to geofoam applications include increased vulnerability to applied external loads, need to prevent contact with gasoline and other organic fluids or vapors, high flammability, and cost.

5.1.1.6 Use of Crushable Material to Limit Maximum Loads on the Pipeline

Controlled strength material around the pipeline can be used to limit the lateral loads that can be exerted normal to the pipe wall. Geofoam and cellular concrete are two materials

well-suited for this purpose since they can experience large compression strain under near-constant compression load. Cellular concrete is a mixture of sand, cement, and water to which a foaming agent or polystyrene beads are added to create small air pockets. The use of crushable material as a mitigation measure is typically only a practical consideration for fault crossings in rock or rock-like materials where very large lateral soil-spring forces can be generated and excavating a trapezoidal trench that can be filled with loose granular material is difficult or impractical. Controlled-strength materials improve pipeline response by allowing the pipe to bend in a more gradual manner to accommodate the imposed ground displacement.

The distance from the pipeline that is to be filled with controlled-strength material is largely governed by the amount of compressive irrecoverable strain that can be accommodated before the material begins to exhibit much higher compressive strength. This strain level is commonly referred to as the lock-up strain. The lock-up strain for cellular concrete can vary from 15% to 35%. The lock-up strain for EPS or XPS geofoam can vary from 25% to more than 50%.

5.2 Ground Displacement

The capacity of a buried pipeline to withstand ground displacement components can be improved by maximizing the distance from the deformation zone (fault rupture, landslide, lateral spread, etc.) to points of virtual anchorage, typically side bends, overbends, and sagbends. Sharp bends, tees, branch fittings, valves, etc. also will have a tendency to anchor the pipeline against axial movement and should be avoided within or near a zone of ground displacement. Good design practice is to provide a straight segment of pipeline as long as practical through and beyond the ground displacement zone to maximize the length of pipeline available to distribute strain.

5.3 Isolation from Ground Displacement

Soil loads on buried pipelines are the result of relative movement between the pipe and the surrounding soil. This relative movement can be minimized or eliminated by providing space around the pipeline that is greater than the relative movement associated with poor pipeline response. Isolating the pipeline from ground displacement is generally practical only when the ground displacements are relatively small, the length of pipeline requiring isolation is relatively short, or the pipeline diameter is relatively small.

Mitigation concepts using culverts allow the pipeline to respond in a manner similar to an on-grade condition. The term culvert refers to any buried structure built partially or completely around the pipeline to provide an unobstructed space for the pipeline to deform in a direction transverse to its axial alignment. Three conceptual culvert configurations are illustrated in Figure 5.5. Culvert concepts are essentially specialized casings and the same problems that can arise for cased pipelines generally apply to culverts. In addition, caution is needed to assure that axial loads from thermal changes or internal pressure do not lead to buckling of the pipe within the culvert. Axial buckling can typically be prevented by incorporating bends or expansion loops in the pipeline.

5.2 Modify Pipeline Configuration

In some cases, minor modifications to proposed or existing pipeline configurations can greatly improve performance. Such modifications include increasing the pipe wall thickness, increasing the strength and toughness of the pipe material, and replacing sharp bends and elbows with induction bends or gradual pipeline field bends.

Increasing the pipe wall thickness increases the allowable longitudinal compression strain and increases the bending and axial strength of the pipeline relative to the soil. Avoiding sharp bends and elbows can minimize the degree to which the pipeline must accommodate the ground displacement through local bending.

Isolation valves, automatic or remotely controlled, may be provided on each side of the zones of ground displacement to mitigate the consequences of possible pipeline ruptures. It should be recognized that the use of automatic or remotely-controlled valves on liquid lines also involves consideration of the effects of hydraulic transients to avoid having a rapid shutdown result in risks from possible overpressurization more significant than the risks from the seismic hazards.

5.3 Modify Emergency Response Procedures

Knowing that a pipeline is susceptible to earthquake damage and planning for the damage in the event an earthquake occurs is often sufficient to assure that the performance criteria for the overall system are met. Planning for pipeline earthquake damage is not fundamentally different than planning for damage from any other source. However, normal emergency response procedures are typically inadequate for dealing with post-earthquake recovery, because there may be multiple emergencies occurring simultaneously at a time when the general civil infrastructure is damaged (e.g., roads, bridges, electric power, communication) and access to the pipeline or coordination of inspection and repair efforts may be impeded.

Knowledge of the conditions under which emergency response procedures will be implemented is vital. A partial list of some conditions to consider is provided below:

1. Normal electric power may be lost for several hours to several days.
2. Water and sanitary services may be lost for several hours to weeks.
3. There likely will be reduced demand for product.
4. Telephone services, wire and wireless, may be interrupted or heavily congested.
5. Highway bridges and over passes may be damaged, resulting in road closure.
6. Traffic may be congested due to road damage and emergency activity.
7. Personnel may be unavailable due to property damage, injury, or family needs.

8. Maintenance and construction contractors may be unavailable due to increased demand for their services or damage to their facilities.
9. Repair crews may be hampered by food and fuel shortages and interruption of electric power, water, and sanitary services.
10. Damage to adjacent facilities may hamper access to pipeline repair areas.
11. Replacement pipe, fittings, and valves may be unavailable in the quantities required.

Planning for rapid earthquake response needs to be coordinated with local and regional government authorities, as well as key customers. Identifying potential post-earthquake response needs with local and regional governments can minimize delays in accessing damaged portions of the system and problems that may arise with securing a work site. Also, governmental agencies can provide important information on the earthquake hazard and expected levels of earthquake damage to buildings and services such as electricity, water, sewer, and transportation. Making customers aware of the potential severity and duration of service interruption can allow them to incorporate the information into their own emergency response planning.

Finally, it is not sufficient to simply have an earthquake response plan. Because of the infrequent nature of earthquakes, regular earthquake simulation exercises are necessary to maintain personnel readiness and identify potential planning deficiencies. These exercises should be coordinated with local and regional planning exercises to identify coordination issues and take full advantage of current information on earthquake hazards and other earthquake damage that could potentially jeopardize a rapid response to pipeline damage.

C1.0 GENERAL PROVISIONS

The presentation of these guidelines utilizes a format in which a concise set of general procedures is provided separate from more detailed discussion. This Commentary is meant to provide the necessary background and discussion in order to properly implement the recommendations contained in Part I: Guidelines and Recommended Procedures. This format was selected to provide easy reference for users once they have familiarized themselves with the entire guidelines document.

C1.1 Application

These guidelines should not be interpreted as a set of minimum requirements for a particular application. Instead, the goal is to provide consistency among the definition of seismic hazard, analytical methods, and acceptance criteria. Modifications to the level of analysis or the definition of seismic hazard will necessarily lead to a change in the acceptance criteria.

The acceptance criteria in these procedures are based upon consideration of steel pipe with butt-welded pipe joints. This has been the typical configuration for natural gas and liquid hydrocarbon transmission pipelines for the past 40 to 50 years. These guidelines do not cover piping configurations that include appurtenances such as valves, meters, filters, branch line connections, flange connections and other configurations with deformation limits considerably different from butt-welded steel pipe.

C1.2 Process

The procedures in these guidelines are consistent with the philosophy that the earthquake hazards are defined in a conservative fashion, and the subsequent pipeline assessments are based upon more liberal strain acceptance criteria. With this philosophy in mind, the performance goal for a pipeline defines the expected occurrence rate of the earthquake hazard.

Defining the target performance goal for assessing pipeline response to seismic hazards is a fundamental and critical task. It is incumbent on the pipeline owner to determine an appropriate level of seismic risk considering public safety, service reliability to customers, regulatory agency approval, potential property and environmental damage, and protection of capital investment. The definition of performance goal should be in terms of an acceptable median annual probability for experiencing an unacceptable level of pipeline performance (e.g., continued function or pressure integrity).

Identification and quantification of seismic hazards requires expertise in the fields of geology and seismology. In addition, quantification of the soil properties necessary for the evaluation of pipeline response requires expertise in the field of geotechnical engineering. It is assumed that sufficient information on the seismic hazard and soil conditions is available for use with these procedures. In most cases, estimates of soil

strength parameters will require subsurface site investigations and laboratory tests of soil samples.

While the scope of these procedures is directly applicable to earthquake-generated hazards, the procedures can be extended to other non-seismic hazards that produce permanent ground movements along a pipeline alignment such as slope movement and ground settlement provided such hazards are defined in a similar fashion (i.e., the hazards are directly related to the target performance goal). These procedures may also be extended to other pipeline systems (e.g., chemical, water) provided adequate consideration is given to the operational characteristics that differ significantly from natural gas and liquid hydrocarbon pipelines. Such characteristics may include alternate pipe material and alternate pipe construction methods.

The approach in these guidelines differs from typical practices embodied in building codes that rely on partial safety factors to achieve a target level of reliability. The simplified approach in these guidelines is justified by the current inability to reasonably quantify the uncertainty in estimating various seismic hazards, soil loading parameters, and pipeline performance under specific strain levels. For most building codes, conservatism in design methods and specification of safety factors are specifically intended to result in a probability of not meeting a performance objective (e.g., building collapse) that is less than the probability of experiencing the design seismic ground motions. As an example, U.S. building codes are intended to achieve a mean annual probability of building collapse from earthquakes no greater than $4x10^{-4}$. The building design is based upon earthquake ground motions with a mean annual probability of exceedance of approximately $1x10^{-3}$ to $2x10^{-3}$. Thus, use of these guidelines with seismic hazard definitions based upon design values specified in building codes will not generally result in the same level of performance intended for buildings. Instead, to achieve a level of reliability that approximates that for buildings, these guidelines require that the annual probability of exceeding seismic hazards be the same as the probability of not meeting the building performance objective. Using the above example for the U.S. leads to defining the mean annual probability of exceedance for the seismic hazard as $4x10^{-4}$.

In actual practice, it is more typical for performance goals to be defined by mean annual probabilities of $1x10^{-3}$ to $2x10^{-3}$ for experiencing loss of pressure integrity from a seismic event. Adopting lower performance goals compared to what are intended for new buildings is justified considering the relatively low potential for significant safety consequences from damage to natural gas and liquid hydrocarbon pipelines compared to large occupied buildings.

In some cases, pipeline operators may wish to achieve a very high level of reliability for especially critical pipelines. The approach in these guidelines is to introduce additional conservatism by considering less frequent and more severe earthquake hazards. Users are cautioned that this approach may not be appropriate when performance goals dictate that earthquake hazards with mean annual probabilities of exceedance are considerably less than $4x10^{-4}$. Caution is required because of the fact that the majority of the available methods for estimating seismic ground displacements are empirical and based upon a limited set of historical observations. Because of this, extrapolation to extremely rare

seismic events can be highly imprecise. If it is necessary to achieve extraordinarily high levels of reliability, the necessary conservatism needs to be achieved through a combination of a low likelihood of experiencing a seismic hazard and a high likelihood (higher than considered in these guidelines) of achieving specific pipeline capacity without compromising pipe performance (e.g., maintaining operability or pressure integrity). Establishing appropriate levels of conservatism in hazard definition and pipeline capacity will typically require a more formal formulation incorporating state-of-the-art methods that are beyond the scope of these guidelines.

C1.3 Alternate Procedures

The relationships for soil loads and pipeline limit states are based upon information that can be obtained readily through available construction records or standard geotechnical investigations. Field and laboratory tests of actual pipelines and soil conditions are generally much better representations of actual behavior. However, specific tests are not typically performed because of the relatively high costs and difficulty in extrapolating data from a few locations to represent conditions present over long sections of the pipeline alignment. For these reasons, the procedures have been formulated based upon what is believed to be readily available information.

Nonlinear, large-displacement finite element analysis, with the pipeline represented by beam-like elements with nonlinear stress-strain properties, is the recommended approach. In some cases, bounding analyses using simplified calculation procedures may be sufficient to assess pipeline response. It is also possible to perform more complex finite element analyses with the pipeline represented by shell-elements. Such refined analyses are not prohibited by these guidelines and have been shown to provide good correlation with pipeline behavior in controlled tests. However, it should be recognized that the methods described in these guidelines for determining soil restraint boundary conditions do not apply to finite element models represented by shell elements. Furthermore, it is doubtful that shell element soil restraint properties could be developed without extensive, full-scale test programs. Consequently, the use of shell element models for the pipeline should be restricted to investigations of localized response of the pipeline where non-linear deformations (e.g., wrinkling, buckle formation) are expected.

C1.4 Required Information

The information requirements listed are based upon data necessary to implement the procedures in these guidelines. The sources of this information may include mill tests, laboratory tests, geotechnical investigation, and seismic hazard assessment.

C2.0 QUANTIFYING SEISMIC HAZARDS

Seismic hazards affecting buried pipelines are divided into two categories: permanent ground deformations (surface faulting, lateral spread movement, subsidence, landslide) and dynamic strains from wave propagation.

The response of buried pipelines to inertial shaking effects (i.e., the pipeline vibrating within the soil) are not considered in these guidelines, as past experience and prior studies show that these do not have a significant effect on pipeline stress or strain (Nelson and Baron, 1981; Parnes and Weidlinger, 1979).

C2.1 Surface Faulting

Faulting is the deformation associated with the relative displacement of adjacent parts of the earth's crust. Fault displacements can occur rapidly during an earthquake (duration on the order of one to several seconds). In addition, relatively minor displacements may accumulate gradually over many years as aseismic creep.

Faulting that results in surface rupture is an important consideration for buried onshore pipelines, because pipelines crossing fault zones must deform longitudinally and in flexure to accommodate ground surface offsets. For offshore pipelines that are simply laid on top of the seafloor, fault movements are generally of little, if any, consequence. Due to the unrestrained pipeline configuration, strains induced by fault movement will be only a small fraction of those that would be developed in a buried pipeline with similar dimensional characteristics and properties. It is possible that offshore faulting could produce a vertical offset that would cause a segment of the pipeline to be elevated above the seafloor for a short distance, and, hence, cause concern for vortex-induced oscillations from water currents. It is not practical to attempt to design for such a remote possibility in advance, particularly considering that fatigue damage to the pipeline would not occur for some time, probably years. For offshore pipelines that are intentionally buried (typical for pipelines in less than 100 feet of water) or are expected to become buried as a result of sea bottom sediment transport processes, the treatment of offshore pipelines mirrors that for onshore pipelines.

Faults are classified on the basis of their direction of movement with respect to the ground surface. The various types or classifications of fault movement are illustrated schematically in Figure C2.1. A strike-slip fault is one in which the predominant component of ground movement is horizontal displacement. If the movement of one side of the fault when viewed from the other side is to the right, the fault is called a right-lateral strike-slip fault. When the movement is to the left, the fault is called a left-lateral strike-slip fault. Normal-slip and reverse-slip faults are those in which the overlying side moves downward and upward, respectively, in relation to the underlying side of the fault. In many cases, faults exhibit a combination of strike-slip and normal or reverse-slip movements.

The effect of right-lateral strike-slip movement on a buried pipeline is illustrated in Figure C2.2. For some faults, the maximum credible surface movements can be as large as 10 meters for strike-slip faults and 5 meters for normal-slip faults. In some cases, ground movements for a particular fault may occur over a number of closely-spaced parallel fault traces or splays within a fault zone, and consideration must be given to the total as well as the individual movements within the zone.

The evaluation or design of a pipeline crossing a fault generally requires the following information:

1. Location of the pipeline-fault intersection and error bounds on location (e.g., ±50 meters).

2. Expected allocation of fault slip among multiple fault splays, if applicable.

3. Angle of intersection of the fault with the pipeline alignment at the point of crossing.

4. Type of slip expected (e.g., strike-slip, normal-slip or reverse-slip).

5. Width of the zone of disturbed ground. For strike-slip faults, the zone of ground distortion will be on the order of 2 to 5 meters. For normal or reverse faults, the principal zone of surface disturbance is typically on the order of 5 to 15 meters. For reverse faults, secondary surface cracking and heaving may occur over a distance of as much as 200 meters on the hanging wall block of the fault.

6. Fault dip angle.

7. Design fault displacement (defined as orthogonal components of displacement in three-dimensional space).

Generally, a fault is considered active if it can be demonstrated to have displaced the surface of the ground during the Holocene Epoch, i.e., within the past 11,000 years. This, of course, assumes that faults with evidence of such historic movement will be the ones that move again. This has not always been the case. The 1999 Hector Mine earthquake in southern California occurred on a fault that was shown on fault maps to be "inactive," albeit some geologists believe that the fault rupture was closely tied to an adjacent active fault system.

In some jurisdictions, fault activity may be defined by regulatory bodies. In California, the Alquist-Priolo Special Studies Zones Act of 1972 provides special regulations regarding land uses near faults that are "well defined" and "sufficiently active." In this context, well-defined implies that the fault can be detected by a trained geologist as a physical feature, at or just below the ground surface. "Sufficiently active" is defined as having evidence of Holocene surface displacement along one or more segments.

Unfortunately, there are no reliable means for predicting the probability of future fault displacements. The basic mechanisms that govern such phenomena are measured in terms of thousands of years, i.e., orders of magnitude greater than the design life of the

pipeline. Consequently, for the evaluation or design of pipeline crossings of active surface faults, it is necessary to utilize judgment based upon experience and consideration of the best available data.

The preferred method for estimating fault displacement is to rely on historical data on fault displacement or the findings from site-specific studies that may include examination of topographic features, observations of geomorphic features, or trenching across the fault to identify historical evidence of past fault displacement. For most pipelines, this preferred approach is only practical where site-specific studies have previously been performed for the purposes of refining regional seismic hazard estimates. In lieu of site-specific information, estimates of fault displacement often rely on empirical methods tempered by the judgments of individuals experienced in their development and limitations.

C2.2.1 Empirical Models for Estimating Fault Displacement

A number of investigators have compiled statistics regarding historic fault displacements as a function of earthquake magnitude, fault rupture length, and other related parameters. The most recent compilation was done by Wells and Coppersmith (1994) using a worldwide data base of source parameters for 421 historical earthquakes. In their study, Wells and Coppersmith developed a series of empirical relationships among moment magnitude, surface rupture length, subsurface rupture length, down-dip rupture width, rupture area, and maximum and average displacement per event.

The data sets for the two regression equations given in these guidelines include displacement data for all types of slip, i.e., strike-slip, normal-slip and reverse-slip faulting. Regression equations that are unique for particular slip types are also available in Wells and Coppersmith, but the correlation is unsatisfactory for reverse faults, probably due to the difficulty in making reliable field observation of reverse-slip movements. Wells and Coppersmith (1994) recommended using the regressions for an aggregate of “all” types of slip.

The surface rupture length is not necessarily the entire length of the fault trace visible on the surface but, rather, it is the maximum length of the fault segment crossing the pipeline that, by reasonable and qualified judgment, can be expected to rupture during an earthquake. Such judgments should be made by geologists with knowledge of regional seismotectonics and with reference to site-specific information and studies. As an upperbound estimate of fault displacement, it may be appropriate to assume that the fault can rupture along its entire length. However, this could lead to unnecessarily conservative design displacements.

In regions where probabilistic or deterministic ground shaking hazard maps have been developed, information on fault length may be readily available (e.g., consider the fault map data provided for use with the 2000 International Building Code in the U.S.) Other information sources include the U.S. Geological Survey (U.S.), Canadian Geological Survey, Pacific Geological Survey (British Columbia, Canada), and the California

Geologic Survey. In the absence of published information, it may be necessary to conduct geologic field studies in order to estimate fault length. Surface expression of fault movement can be considered unlikely for earthquakes with moment magnitudes less than 6.0.

The potential variability in the empirical expressions for fault displacement can be illustrated by a sample calculation. Using equations (2-1a) and (2-1b) for a surface rupture length of 75 km yields mean maximum and mean average fault displacements of 3.4 m and 1.7 m, respectively. Using equations (2-2a) and (2-2b) with a moment magnitude of 7.5, yields mean maximum and mean average fault displacements of 4.9 and 2.4 m, respectively. For the case of a fault with a 75 km surface rupture, the maximum and average fault displacements within one standard deviation of the mean are 1.3 m to 8.7 m and 1.8 m to 7.6 m, respectively. The range is somewhat larger for fault displacements estimated based upon earthquake magnitude. Thus the empirical formulae produce a range of fault displacements that vary by a factor of about 4 to 7 in order to capture the actual fault displacement slightly better than half of the time. For this reason, projects that pose an extreme threat to safety or the environment (e.g., large LNG facilities, nuclear power plants) typically require site-specific investigations to better define fault displacement. Site-specific investigations may include trenching, soil borings, and paleoseismic studies to establish the approximate dates of prior fault displacement and the amount of displacement that has occurred in past earthquakes. For most pipeline projects, however, this level of effort is not justified by the potential consequences of earthquake damage.

□2□□2□ □r□□□□□□□□D□□□□□□□ □□□□ □□ □□□□□□□□

For the design of a pipeline crossing a fault, the relative displacement of the soil block on one side of the fault must be known in a three-dimensional sense relative to the soil block on the other side. The user should be aware that it is not uncommon for geologists to define fault displacement in terms of the resultant two-dimensional displacement vector in a vertical plane parallel to the strike of the fault. In other words, the fault displacement is the *resultant* of the observed vertical offset of the ground surface and horizontal displacement parallel to the fault.

If the fault is known to be predominantly strike-slip, it usually is sufficient to assume that the resultant displacement will be parallel to the fault strike. However, in the case of reverse faults, the nature of the fault displacement may be highly variable due to an irregular (nonlinear) surface trace such that the displacement at the pipeline crossing may be a combination of horizontal, vertical and compressional-extensional displacement components relative to the strike of the fault.

Fault displacement estimated using the Wells and Coppersmith regression equations is the projection of a resultant fault displacement on a vertical plane that intersects the fault strike at the surface. The database for the regression equations does not include the vertical and horizontal components of displacement in the vertical plane that intersects

the strike, nor does it include the transverse component of reverse-slip or normal-slip components of displacement perpendicular to the fault strike.

Empirical approaches, other than those developed by Wells and Coppersmith, are available for estimating fault displacement. These guidelines do not prevent the use of these approaches but encourage the use of alternate relationships that may be more appropriate for specific regions or fault systems.

The recommended approach to determine three-dimensional fault displacement components from fault displacement defined in a manner similar to the Wells and Coppersmith regression equations requires some estimate of the fault geometry and regional seismic stress regime as defined by (1) the angle of intersection between regional stress azimuth and fault strike, β, and (2) the fault dip angle, δ.

The displacement of a hypothetical fault displacement is shown in Figure C2.3. The net displacement in a vertical plane parallel to the fault strike is the resultant of two of the three orthogonal components of fault displacement, i.e., the horizontal component of slip, H_F, parallel to and the vertical component, V_F, perpendicular to the strike of the fault. The individual horizontal and vertical displacement components, H_F and V_F, as well as the transverse component of fault displacement perpendicular to the fault strike, T_F, are unknown.

If it is assumed that the total fault displacement, D_{FS}, is in the direction of the regional stress azimuth, the total fault displacement and its constituent orthogonal displacement components can be determined from the geometry of right triangles. The resulting relations for the three orthogonal components are given in equations (2-3b), (2-3c) and (2-3d) in these guidelines.

The values for the fault dip angle provided with equation (2-3) are approximate values that are believed to be generally representative of the database used in the development of the Wells and Coppersmith empirical relationships. It is possible that empirical relationships developed for specific seismic regions are available. In this case, the generic fault dip angles provided with equation (2-3) may not be appropriate. In general, the determination of fault movement components is best left to an experienced geologist having knowledge of local plate tectonics and the regional stress regime in the earth's crust.

□2□□□□ D□□□□□□□□D□□□□□□ □□□□

Recommended design fault displacements are based upon the potential consequences associated with pipeline damage and defined in terms of the expected maximum or average fault displacement consistent with the probability of exceeding pipeline performance criteria established by the pipeline owner. The process for determining design fault displacement consists of three basic steps:

1. Determine the performance requirements for the pipeline in terms of an average annual probability of exceeding strains associated with maintaining normal operability or pressure integrity;

2. Determine the average and maximum fault displacement consistent with the probability established in Step 1; and

3. Determine design fault displacement values by modifying the fault displacements in Step 2 based upon the consequences associated with the pipeline not meeting its performance objectives, the average probability of the occurrence of fault displacement, and the acceptable annual probability for the pipeline exceeding its performance objectives.

Pipeline performance requirements are established by the pipeline owner and will typically vary depending upon the factors discussed in Section C1.2.

The maximum fault displacement that occurs during a seismic event typically occurs along a short length of the fault rupture, with lesser amounts of movement along most of the fault rupture length. For faults with no information from historical rupture patterns or detailed fault studies, estimating the distribution of maximum displacements along the fault rupture length is extremely uncertain. Since that maximum is generally considerably greater than the average displacement (about double), it is reasonable to use a value smaller than the maximum credible displacement when developing design values for engineering design at active fault crossings.

Determination of fault displacements consistent with the performance goals of the pipeline requires considerable judgment, particularly for faults where the episodic nature of earthquake activity has not been investigated. Reduction of fault displacement estimates for design are warranted when the average probability of surface rupture is less than the performance goals of the pipeline. The approach adopted in these guidelines is to simply factor the fault displacement estimates by the ratio of the acceptable probability for the pipeline not meeting its performance goal by twice the average probability associated with the fault displacement estimate. The factor of 2 on the average probability of fault displacement can be reduced if there is good information on fault occurrence based upon historical records or fault trenching investigations.

The approach for estimating design fault displacement in these guidelines implicitly accepts the risk associated with uncertainties in understanding fault behavior. Some of these uncertainties include the following:

1. Actual displacement on a fault may be considerably greater than that produced by earthquakes of similar magnitude.

2. The likely fault displacement, based upon estimates of fault slip rate and expected earthquake magnitude (the most common approach), is not a reliable means to assess the difference in the probability of fault displacement in the near future (i.e., 50-year to 100-year time frame).

C2.2 Peak Ground Acceleration

Estimates of peak ground acceleration (PGA) are necessary in order to estimate potential seismic hazards related to liquefaction, lateral spread movement, and slope stability. Peak ground accelerations are estimated using empirical attenuation equations that relate the dissipation of earthquake energy with distance from the source of the earthquake. Attenuation relationships utilize data recorded from strong motion accelerographs. The acceleration time history data are typically segregated according to the local site conditions on which the accelerograph is founded, such as hard rock, soft rock, firm soil, and soft soil. In addition, many recent attenuation relationships segregate the data by the type of faulting (e.g., strike-slip, normal-slip, reverse-slip). Attenuation relationships also have been developed to represent spectral accelerations at various frequencies. However, only PGA is of importance for use in these guidelines.

All attenuation relationships require as input the earthquake magnitude and a measure of distance from the earthquake source. The selection of a particular measure of magnitude (e.g., moment magnitude, surface wave magnitude, and local magnitude) and distance (e.g., epicentral, hypocentral, and shortest distance to fault plane) is largely a matter of personal preference on the part of the individual developing the relationship. Figure C2.4 provides a definition of earthquake source parameters often incorporated into attenuation relationships.

There is typically a great deal of scatter in the recorded ground motion data for a particular distance from the earthquake source. Directivity associated with the orientation of fault rupture is believed to be a significant factor in the observed scatter. Another factor in the amount of observed scatter is local interaction of seismic waves as they propagate to a single site from multiple locations along the fault rupture surface. This scatter introduces uncertainty in the attenuation relationships that is represented by the random-error term *E*. The random-error term is typically a function of earthquake magnitude.

Setting *E* to zero results in a best estimate of the fit of the attenuation equation to the data. The random-error term is used to estimate the probability that accelerations might be different than that estimated from the best-estimate equation. In application, the random-error term is multiplied by a factor representing the number of standard deviations from the mean producing the desired standard normal probability value. Thus, using 1(*E*) produces an estimate of PGA that envelops 84% of the data, 1.65(*E*) produces an estimate of PGA that envelopes 95% of the data, and 2(*E*) produces an estimate of PGA that envelops 98% of the data.

Some measure of the precision with which attenuation relationships estimate PGA can be gained by examining the factors representing ±25% variation from the mean. This corresponds to the factors on the mean that would provide a range of accelerations that have a 50% chance of occurring. A mean plus 25% estimate corresponds to an estimate that envelops 75% of the data or is 0.68 standard deviations from the mean. A mean minus 25% estimate corresponds to an estimate that envelops 25% of the data or is –0.68

standard deviations from the mean. For the two attenuation relationships provided, the random-error terms for a magnitude 7 earthquake are 0.41 for the near-source earthquake equation and 0.75 for the Cascadia earthquake. The corresponding factors on the mean estimate to give a 50% chance of experiencing the estimated PGA are computed as follows:

Near-Source: Factor = $e^{0.68(0.41)} = 1.32$

Cascadia: Factor = $e^{0.68(0.75)} = 1.67$

Assuming the PGA estimate was 0.5 *g*, the range of PGA values having a 50% chance of occurrence is 0.38 *g* to 0.66 *g* for the near-source earthquake and 0.30 *g* to 0.84 *g* for the Cascadia earthquake. This example illustrates the wide variability typically encountered in estimating seismic hazards. It is also clear that stating estimates of PGA within increments of 0.05 *g* or greater is generally sufficient.

Since attenuation relationships are developed from recorded ground motion data, users should attempt to identify attenuation relationships developed for the specific region of interest. If such relationships cannot be identified, the selected attenuation relationship should be based upon records from regions that are tectonically and geologically similar. Often, multiple attenuation relationships may be identified as appropriate for a particular location. Where possible, it is recommended that peak ground acceleration be estimated as the average of at least three representative attenuation relationships.

A good source of information for attenuation relationships applicable to the United States is Seismological Research Letters (SSA, 1997). This reference provides a collection of recently developed attenuation relationships and is a starting point for identifying attenuation relationships for locations other than the west coast of the United States. For other parts of the world, it is generally necessary to identify applicable attenuation relationships from past earthquake investigations, seismic hazard analyses, or accepted practice in past estimates of seismic ground motion hazards for the region.

C2.3 Liquefaction

Liquefaction is the transformation of a saturated cohesionless soil from a solid to a more liquid state as a result of increased pore-water pressure and concomitant loss of shear strength. Loss of shear strength gives rise to bearing failures and large deformations in surface structures founded on liquefied soil. Liquefaction often leads to the formation of sand boils, mud volcanoes, fissures and other channels through which water and sediments are ejected. These ejections cause volume loss resulting in differential settlement even though no significant lateral movement occurs.

Liquefaction is a phenomenon that is generally limited to saturated sandy soils that have been deposited in the Holocene (the past 11,000 years) and most commonly to fluvial sediments deposited in the past 1,500 years. These characteristics typically limit consideration of liquefaction to locations where the water table is less than 15 m below

the ground surface. Liquefaction is most likely to occur within a kilometer of bodies of water (e.g., shorelines, streams, drainage channels) and within deltaic deposits where the water table is typically shallow.

Existing maps and databases pertaining to surficial geology should be used to identify areas with soils of depositional characteristics and geologic age that are known to have liquefied in previous earthquakes. The procedures proposed by Youd and Perkins (1978) should be followed. Table C2.1 (Youd and Perkins, 1978) summarizes the liquefaction susceptibility of various deposits according to geologic age. For most pipeline projects, it is only necessary to consider sedimentary deposits with high or very high liquefaction susceptibility.

C2.[illegible] [illegible]

Collecting information necessary to assess the potential hazards from liquefaction requires site-specific subsurface data. Unless adequate subsurface data are available from past projects at the site of interest, site investigations consisting of subsurface sampling, standard penetration tests, cone penetrometer tests, and laboratory tests are required.

Assessing liquefaction potential is based upon both peak ground acceleration and earthquake magnitude. Estimating peak ground acceleration at the site of interest can be performed using probabilistic or deterministic approaches. The deterministic approach is based upon selecting a magnitude for a particular fault and using attenuation relationships that relate peak ground acceleration to magnitude, distance, local soil conditions, and type of earthquake faulting. The probabilistic approach is similar to the deterministic approach only in the sense that attenuation relationships are used to relate peak ground acceleration to earthquake magnitude, distance, and type of earthquake faulting.

In a probabilistic approach, the effects of numerous earthquake sources, each with different rates of occurrence for earthquakes of various magnitudes, are included. Additional information on probabilistic seismic hazard estimation is provided in Appendix C. The results of a probabilistic approach for estimating PGA are typically represented in maps of PGA contours for different annual probabilities of exceedance (Figure C2.5) or site-specific curves representing the variation of PGA with annual probability of exceedance (Figure C2.6). For liquefaction assessment, it is necessary to examine the contribution of earthquake magnitudes and distances to the ground shaking hazard. This is termed deaggregation of the hazard. The deaggregation of the hazard is often represented by plots of magnitude and distance contributions such as those shown in Figure C2.7. There are no established rules for selecting an appropriate magnitude and distance from a deaggregation of the probabilistic hazard analysis. Three common approaches are to select either the mean contribution, estimates enveloping mean plus one standard deviation (84%) of the contributions, or a magnitude and distance combination that has the largest contribution to the probabilistic hazard. These approaches are illustrated in Figure C2.7.

Assessment of potential liquefaction hazards requires site-specific information on the density and grain-size distribution of subsurface soil layers. As a general consideration, site-specific investigations should be performed at the types of areas listed in Table C2.1 as having moderate to very high risk of liquefaction where the peak ground acceleration is expected to be greater than about 0.15 g.

The procedures presented for assessing liquefaction are based upon the findings of a 1997 workshop (Youd and Idriss, 1997). The proceedings of this workshop provide an excellent summary of the state-of-practice in assessing liquefaction hazards. Two changes in the manner in which liquefaction is assessed resulting from the workshop deserve mention. First, the workshop participants agreed to modify the hand drawn curve developed by Seed and Idriss (1982) to reflect a minimum *CRR* value of 0.05. The modified curve for which the equations in these guidelines are developed is shown in Figure C2.8. Second, the workshop participants agreed that the magnitude scaling factors originally developed by Seed (Seed and Idriss, 1982) were far too conservative for earthquakes with magnitudes less than 7. Although specific magnitude scaling factors were not recommended by the workshop participants, the recommended range of magnitude scaling factors represent an increase of 50% to 100% in the *CRR*.

C2.2.2 Displacement Potential and Resistance

Vertical pipeline movement resulting from buoyancy forces has not been a significant hazard to buried onshore pipelines in past earthquakes. The combination of limited displacement potential and the length of pipeline typically exposed to liquefaction generally prevents the development of significant pipeline strains.

Onshore pipelines located above the water table are not subjected to relative buoyancy forces. Pipelines located beneath the water table in liquefaction-susceptible soils can experience vertically upward or downward displacements depending upon the weight of the pipeline with coating and contents, the weight of liquefied soil displaced by the pipeline, and the residual shear strength of the liquefied soil. The time over which the soils remain in a liquefied state is a key variable to determining the amount of vertical movement. No studies to quantify the duration of liquefaction and its effect on movements caused by differential buoyancy could be identified. As a first approximation, the duration of liquefaction can be assumed to be equal to the duration of ground motion sufficient to cause liquefaction, another poorly defined parameter. The procedure in these guidelines is limited to a means to identify the maximum potential movement of the pipeline.

Practically, relatively extreme conditions of buoyancy mismatch appear to be necessary to produce relative pipe movement. This is illustrated by the following example.

Consider an NPS 24 pipe with a wall thickness of 9.5 mm (0.375 inches). The weight of the pipe is 1.42 kN/m (97 lb/ft) and the effective density of the pipe is 4.9 kN/m^3 (31 lb/ft^3). If the total unit weight of liquefied soil is 17.4 kN/m^3 (110 lb/ft^3), the net buoyancy force on the pipe is 3.62 kN/m (248 lb/ft) in the upward direction. It is

assumed that the depth to the centerline of the pipe is 2 m (6.56 ft), the water table is at the ground surface, and the residual shear strength of the liquefied soil is 5% of the effective stress (typical range is 1% to 10%). These assumptions lead to a residual shear strength of only 0.976 kPa (20.4 psf) and a soil resistance to vertical movement of 12.9 kN/m (884 lb/ft) based upon the approaches in Section 4.3.3. Since the soil resistance is about 3.6 times the upward buoyancy force, no movement would be expected.

Given this example, it is expected that vertical movements from pipeline buoyancy will only be a significant hazard for large diameter pipelines within soils expected to exhibit unusually low residual shear strength in a liquefied state. Calculations, similar to those in the above example, can be used to gauge the potential for significant pipeline vertical movement from buoyancy forces.

Evaluating displacements from relative buoyant forces for underwater pipelines can be treated in the same fashion as onshore pipelines. However, buoyancy is typically not an issue for offshore pipelines or inland water crossings as they are required to be negatively buoyant to remain stable on the sea floor. Achieving negative buoyancy is typically done by coating the pipeline with concrete or using discrete weights attached to the pipeline. If buoyancy is an issue, additional conservatism may be warranted to account for the fact that upward movement sufficient to uncover the pipeline will expose it to potential hazards related to flow-induced oscillation and impact with debris carried by water currents (e.g., exposed river crossings).

C2.4.2 Determining Extent of Liquefaction

Although a methodology is presented for estimating the amount of settlement related to liquefaction, assessing pipeline performance also requires an estimate of the extent of liquefaction along the pipeline alignment. Estimating the extent of soil layers susceptible to liquefaction can best be determined from subsurface profiles produced from boring log data. Borings may be drilled at regular intervals along the pipeline alignment to identify the limits of liquefaction. In some locations, detailed maps may be available describing surficial soil deposits and their depositional environments. These may be used for preliminary screening to identify locations more prone to liquefaction.

It is possible that potentially liquefiable deposits extend for several hundred meters along the pipeline. As it is unlikely, based upon historical observations, that the pipeline will experience uniform liquefaction over large distances, some alternate approach is needed to define the extent of a pipeline subjected to relative settlement. This requires the judgment of individuals familiar with the local geology and performing liquefaction assessments.

The graphical methods presented are based upon both observational data (Figure 2.2 from Ishihara, 1985) and laboratory tests (Figure 2.3 from Ishihara, 1990). Both graphs are based upon sands with a fines content less than 5% (“clean” sands). For engineering purposes, this factor can often be ignored as the determination of what constitutes a liquefiable layer and the factor of safety against liquefaction incorporates the presence of

fines content. Applying the charts for other soil types generally overestimates settlement since the presence of fines would tend to fill some voids and reduce the amount of soil grain reorganization responsible for liquefaction-induced settlement.

C2.4 Lateral Spread Movement

Lateral spreads involve the horizontal movement of competent surficial soils due to liquefaction of an underlying deposit (see Figure C2.9). Lateral spreads can be especially destructive to buried pipelines, albeit the degree of damage depends on the magnitude and extent of ground movement and the configuration of the pipeline. Offshore, liquefaction requires special treatment as the amount and extent of ground movements associated with liquefaction can be much greater than for onshore installations.

Lateral spread movement is the most common and one of the most severe earthquake hazards for buried pipelines. Techniques for estimating the magnitude of lateral spread movement have only been developed in the past 15 years.

The simplified approach developed by Youd et al. (1999) based upon multiple linear regression of data from past earthquake observations represents the best available method for estimating lateral spread movement outside of explicit finite element techniques. This approach is a modification of a similar method developed by Bartlett and Youd (1992). The 1999 modifications included data from the 1995 Kobe, Japan earthquake and corrected some of the data records in the 1992 investigation. The expected variability in the simplified approach can be assessed by comparing the predicted lateral spread displacements with the observed displacements. This is provided in Figure C2.10 where it can be seen that nearly all data points are within a factor of two of the predicted displacement.

One weakness of the Youd et al. (1999) approach is its inability to provide information on the extent of lateral spread movement and the variation of ground movement with depth and within the body of the lateral spread. Because of the importance of the spatial variation in ground displacement along the pipeline, the recommended approach for estimating lateral spread movements is to employ an analysis program based upon a finite-element, finite-displacement, or discrete-element representation of the soil. Some examples of programs that have been used in past pipeline projects include DESRA-2 (Lee and Finn, 1978), TENSI-M (Larkin and Marsh, 1982), and SOILSTRESS. Many geotechnical engineering firms also maintain proprietary in-house analysis programs. A comparison between the results of the Bartlett and Youd appoach and the results from a SOILSTRESS analysis are shown in Figure C2.11 for a hypothetical river crossing. In the analyses represented in Figure C2.11, the Bartlett and Youd approach was used to benchmark the maximum surface displacements estimated by the SOILSTRESS analysis. With this benchmark established, the SOILSTRESS results are then used to determine the variation with respect to depth below the ground surface for relative ground movements normal to the river.

C2.5 Landslides

Landslide activity most commonly triggered by earthquake shaking includes rock falls, disrupted soil slides, rock slides, soil slumps, soil block slides, and soil avalanches (Varnes, 1978). Several common types of landslides are illustrated in Figure C2.12. Except for rock avalanches, locations susceptible to earthquake triggered landslides are most often associated with areas of past landslide activity. The most significant landslide hazards that can affect buried pipelines are slumps, shallow slides, and deep slides. Slides can occur onshore on relatively steep slopes or offshore in soft sediments on relatively shallow slopes. Landslides may develop into debris flows and impart large dynamic loads on the pipeline. For offshore pipelines, turbidity currents created by the slide may also lead to significant loads on the pipeline.

Slumps and shallow slides are caused primarily by inertial forces, but are often assisted by densification of loose soil or liquefaction of underlying sediments. These movements occur mostly along the margins of embankments, cut-and-fill slopes, and slopes with relatively shallow cover in hilly or mountainous terrain.

Deep slides involving significant components of translation and rotation of a soil mass often develop catastrophically and affect large areas. A landslide frequently causes underthrusting in soils near the base of its slope, so that substantial compression and bending may be transferred to pipelines located there.

Areas of past landslide activity can be identified through reconnaissance of the pipeline alignment and stereo aerial photographs or sidescan sonar for offshore pipelines. Earthquake-triggered landslides typically occur during the earthquake. If the earthquake forces are insufficient to completely develop a failure plane, earthquake-related landslides may occur several days following the earthquake due to reduced resistance to slide movement.

Reconnaissance of a pipeline alignment can be used to identify and estimate the relative activity of existing slides. The findings from the site reconnaissance can be used to modify new pipeline alignments to avoid many potential landslide hazards. Determining the amount of expected deformation requires a site-specific determination of the existing soil strength properties and an assessment of the factor of safety under seismic loading conditions.

In lieu of a detailed assessment of landslide potential, an approximate estimate of potential landslide movement can be made based upon the existing slope and a general description of the near-surface material. This approximate approach is implemented in these guidelines and is to be used as a screening tool to determine the potential for slide movement.

The approach to estimating the potential severity of landslides is based upon bounding relationships for sliding-block displacement developed by Newmark (1965) and estimated levels of acceleration associated with slope instability developed by Wilson and Keefer (1985). The approach to estimating landslide movement developed by

Wilson and Keefer utilizes two relationships based upon Arias intensity, one for the acceleration levels associated with 2 cm or 10 cm of landslide movement and the other for the variation of acceleration as a function of earthquake magnitude.

Wilson and Keefer adopted the use of Arias intensity as a means to avoid explicit calculation of movement using multiple time histories and the methodology developed by Newmark. The Wilson and Keefer approach is not considered generally applicable because of the lack of validation of the Arias intensity relationships for a large number of historical earthquakes.

To provide a general indication of the potential magnitude of landslide movements, a bounding empirical relationship developed by Newmark is used. The analytical model used by Newmark is quite simple. A block resting on a sloping surface is prevented from sliding by the friction force between the block and the surface. Motion of the block is produced when acceleration of the block in the downslope direction exceeds the frictional resistance reduced by the component of block weight in the downslope direction. The factor of safety against block sliding is equal to the resistance to sliding divided by the acceleration acting on the block. The sliding resistance in the downslope direction is the frictional resistance minus the component of block weight in the downslope direction. The upslope movement of the block can occur if the acceleration in the upslope direction exceeds the sum of the friction resistance and the component of block weight in the downslope direction. For the simplified approach used in these guidelines, the Newmark model is identical to the model assumed by Wilson and Keefer. In fact, Wilson and Keefer used explicit analyses using Newmark's approach to develop their approach.

The duration of motion is limited to the time period over which the acceleration exceeds the friction force. Newmark analyzed the movement of a hypothetical block using 5 earthquake time histories normalized to a peak ground acceleration of 0.5 *g*. These analyses did not consider vertical motions and assumed the horizontal earthquake acceleration acted in a direction parallel to the sliding surface. He then examined the fit of several possible analytical expressions to the data, as illustrated in Figure C2.13, and developed several bounding relationships based upon ground velocity, peak ground acceleration and the factor of safety. The equations for estimating landslide displacement in equation (2-18) is based upon an assumption of peak ground velocity equal to 36 and 48 inches per second per *g* (91 and 122 cm per second per *g*) for rock and soil sites, respectively. The bounding displacement equation used to derive equation (2-18) is given by equation (C2-1).

$$D = \frac{V^2}{2gN}\left(1 - \frac{N}{PGA}\right)\frac{PGA}{N} \qquad \text{(C2-1)}$$

where:

D = computed displacement

V = peak ground velocity

PGA = peak ground acceleration

N = resistance coefficient = A_c

g = acceleration of gravity

Rearranging the terms and substituting A_c for N and V as $x(PGA)$ gives:

$$D = \frac{x^2 PGA^2}{2gA_c}\left(\frac{PGA}{A_c} - 1\right) \quad \text{(C2-2)}$$

Equation C2-2 depends on having a velocity ratio, x, the ratio of the peak ground velocity to *PGA*. Several investigators have proposed such relationships and representative values are provided in Table C2.2. Equations (2-15) and (2-16) result from substituting values of 36 inches per second per g (0.91 meters per second per g) for rock and 48 inches per second per g (1.22 meters per second per g) for the velocity ratio, x.

The displacements necessary to initiate coherent and disruptive slides (10 cm and 2 cm, respectively) are adopted from Wilson and Keefer. If the displacements computed using the relationships in these guidelines exceed these threshold values, the potential for landslides exist, and additional geotechnical investigation is warranted. Such investigations typically involve borings to identify different soil deposits, sample retrieval for ascertaining soil strength properties, and slope stability calculations to estimate the amount of landslide movement.

A pseudostatic analysis of slope stability is often used in the assessment of slope movements. The pseudostatic analysis should account for the strength properties of the slope material expected during the earthquake. Pseudostatic analyses represent the effects of an earthquake by applying static horizontal and/or vertical accelerations to a potentially unstable mass of soil. The inertial forces induced by these pseudostatic accelerations increase the driving forces and may decrease the resisting forces acting on the soil. Pseudostatic analyses are not appropriate for soils that build up large pore pressures or show more than about 15% degradation of strength due to earthquake shaking. Stability is expressed in terms of a pseudostatic factor of safety calculated by limit equilibrium procedures. Selection of an appropriate pseudostatic acceleration requires great care; values considerably smaller than the peak acceleration of the sliding mass are usually used.

If conditions exist where such strength loss may occur, it is generally necessary to perform a local site response analysis in order to obtain an estimate of the shear strains produced and the appropriate soil strength for slope stability analysis. Inertial instabilities are most commonly analyzed by pseudostatic, sliding block (Newmark, 1965), or stress-deformation analyses. The Makdisi-Seed approach, based upon the results of sliding-block analyses, is also used frequently.

The pseudostatic acceleration required to bring a slope to the point of incipient failure is known as the yield acceleration. If earthquake-induced accelerations in a slope momentarily exceed the yield acceleration, the unstable soil will momentarily accelerate relative to the material beneath it. Sliding-block analyses can be used to calculate the amount of displacement that occurs. The total displacement depends on the amount by

which the yield acceleration is exceeded (a function of the ground motion amplitude), the time over which the yield acceleration is exceeded (a function of the frequency content of the ground motion), and the number of times the yield acceleration is exceeded (a function of ground motion duration). Given the highly variable nature of ground motion characteristics, computed displacements can be quite variable. The Makdisi-Seed procedure is based upon sliding-block analyses of earth dams and embankments. Knowing the fundamental period of vibration of the dam/embankment and the yield acceleration of the slope, simple charts can be used to estimate earthquake-induced permanent displacements.

It is important to note that the factor of safety based upon equivalent static slope stability assessment can be substantially less than 1.0 before significant sliding displacement occurs. Thus, concluding that large slope movements are highly probable because static slope analyses indicate that the slope cannot withstand the PGA often greatly overestimates the likelihood that a significant landslide hazard exists.

Several commercial software packages are available that greatly simplify the application of sliding-block analysis. Stress-deformation analyses have been used to estimate permanent deformations caused by inertial instabilities. Strain potential and stiffness reduction approaches allow estimation of permanent deformations from relatively simple analyses; their estimates are highly approximate. Although the computational effort is dramatically increased, permanent deformations can be analyzed more rigorously using nonlinear finite-element techniques. As the accuracy of constitutive models for soils improve, the use of nonlinear finite-element analyses is likely to increase. Quantification of slope stability under static and dynamic conditions with analytic techniques for estimating potential slope movements requires special expertise and should be carried out by individuals experienced with the local geologic conditions.

A slope stability analysis is only one part of a comprehensive evaluation of slope stability. Prior to the analysis, detailed information on geologic, hydrologic, topographic, geometric, and material characteristics must be obtained. The accuracy of the analysis will be only as good as the accuracy of this information.

C2.6 Seismic Wave Propagation

Wave propagation strains are related to the incoherency between seismic ground motions at two locations along a linear structure. Well-constructed buried natural gas and liquid hydrocarbon pipelines in good condition generally have not been affected by seismic wave propagation. This is borne out by the lack of a single reported case of failure of ductile, full penetration welded natural gas or liquid hydrocarbon pipeline attributable to wave propagation alone. Recent earthquake experience (Honegger, 1999a) has indicated that wave propagation is a credible earthquake hazard for pipelines only in cases of extremely poor quality girth welds or corrosion defects subjected to very high levels of seismic ground motion. In both instances, these guidelines recommend a case-specific assessment of the longitudinal strain to failure. Such an assessment may require removal of sufficient girth weld samples to develop a statistical description of strain capacity

based upon laboratory tests. Other approaches may involve detailed non-destructive examination, fracture mechanics models, and laboratory tests of a limited number of pipeline specimens. In either case, the details of such case-specific investigations are currently under development in the industry and are beyond the scope of these guidelines.

The only instance where seismic wave propagation has been linked to pipeline is a case study of the 1985 Michoacan (Mexico City) earthquake. The welded pipeline was constructed of 42-inch x 0.313-inch wall API 5L X42 pipe. The reported damage was compressive wrinkling at intervals of approximately 500 feet and occurred in soft clay deposits. The pipeline was influenced by unusual seismic and geologic conditions. Because of the long distance separating Mexico City and the earthquake epicenter (nearly 250 miles), the predominant ground shaking was the result of Rayleigh waves with a relatively high period of incoming waves (2 to 3 seconds). Site amplification contributed to a high peak particle velocity, measured at 35 cm/sec, and the soft lake sediments were characterized by a wave propagation velocity as low as 40 to 100 m/sec. The combination of high particle and low wave propagation velocities would have promoted high ground strains, and the long period would have promoted a relatively large development length for mobilizing shear resistance between the pipe and surrounding soil. O'Rourke (1988) concluded that calculated pipe strains were sufficient to conclude that traveling ground waves were responsible for the damage.

For these reasons, the conclusions of O'Rourke (1988) can, at best, only be considered applicable to geologic settings similar to those from the case study, i.e., very soft deep sediment deposits prone to harmonic excitation by Rayleigh waves. The soil deposits near Mexico City and the tectonic regime surrounding Mexico are unique in this respect. Furthermore, estimating wave propagation strains for any region of similar geology for which strong motion earthquake records do not exist requires an attenuation relationship to estimate ground motions associated with Rayleigh waves, which do not exist.

Although the potential for damage to welded steel pipelines due to seismic wave propagation is generally low, it is occasionally necessary to compute the stress or strain in a pipeline caused by seismic waves. A procedure for estimating apparent wave propagation velocity was first proposed by Newmark (1965). The basis for estimating wave propagation strains is illustrated in Figure C2.14. Earthquake body waves (compression and shear waves) emanate from the earthquake source region as a continuous wave front. Ground shaking at the surface results from the propagation of this wave front up through the near-surface soils. At two locations, A and B, the apparent propagation of body waves is related to the difference in arrival times of the wave front at these locations. The arrival time is a function of the source-to-site distance for A and B and the propagation velocity along the path between A and B. The straight propagation paths shown in Figure C2.14 are a simplification, as the actual propagation paths are likely to be curved as a result of passage through strata of varying density. On the surface, the seismic wave front appears to propagate along the surface at a velocity that is closely related to the propagation of the seismic waves at depth (e.g., 3 km to 30 km). The approach proposed by Newmark (1965) leads to an estimate of maximum ground strain between any two locations on the surface that is proportional to the ground velocity generated by the response of surface soils to the input motion divided by the apparent

velocity of the seismic wave front relative to the surface. In this model, locations directly above the earthquake source zone experience virtually no strain as they experience near-simultaneous arrival of the seismic wave front which translates to a near infinite apparent velocity.

There are some cases that are outside the scope of these guidelines that occasionally merit special consideration. These include transitions between very stiff and very soft soils, penetration into buried valve enclosures, branch connections, pipe fittings, and valves. In addition, pipelines with significant weld flaws, corrosion defects or not connected with full-penetration butt welds (e.g., compression couplings, bell and spigot joints) may also be vulnerable to damage from seismic wave propagation. In such cases, an assessment of the strain capacity of the pipe and comparison with the magnitude of wave propagation strains can be used to judge the expected performance of the pipeline.

C2.7 Transient Ground Deformation

Another potential seismic hazard not related to permanent ground deformation is transient ground deformation (TGD). Transient ground deformations are produced when local site conditions allow weaker surface soils to respond differently from adjacent near-surface soils that are considerably stronger and can possibly damage buried pipelines. This type of behavior has been observed repeatedly in past earthquakes where pipeline damage appears to be more prevalent near the boundaries between strong and weak soils.

Transient ground deformation has been identified as a possible mode of local soil response that can lead to pipeline damage. One of the first investigations to identify transient ground deformation as a cause of pipeline damage was undertaken by O'Rourke (O'Rourke, 1991, Pease and O'Rourke, 1997) in a study of water and sewer pipeline damage in the Marina District of San Francisco following the 1989 Loma Prieta earthquake. O'Rourke postulated that liquefaction in the Marina District caused the hydraulic fill soils to be decoupled from the response of the underlying stiff soils and respond more like a sliding mass.

Following the 1994 Northridge earthquake, investigations into the causes of pipeline damage in Potrero Canyon identified a similar decoupling mechanism as a probable cause of the ground cracking patterns and locations of pipeline damage (Honegger, 2000). The underlying mechanism in Potrero Canyon was postulated to be shear failure within the weak canyon soils that were subjected to a velocity pulse of more than 1 m/s and a period of 5 to 6 seconds. The magnitude and long period of the velocity pulse is attributed to the proximity of Potrero Canyon to the projection of the caU.S.tive fault plane. This type of near-field motion has been recorded in past earthquakes and is commonly referred to as earthquake "fling."

There are no widely accepted procedures for identifying sites susceptible to TGD or estimating potential TGD displacements. A large part of the difficulty lies in the inability to characterize near-field ground motions and the characterization of the strength properties of soils undergoing variable states of liquefaction. The following guidance for

identifying sites potentially susceptible to TGD are provided based upon the sparse amount of field data:

1. Presence of a relatively uniform layer of soil with low shear strength (or high potential for liquefaction).
2. Presence of firm soil or rock adjacent to, or confining, deposits of weak or liquefiable soils.
3. Soft soil sites located in the near-field of a potential earthquake with a likelihood for experiencing ground motions characteristic of earthquake "fling".

Techniques for modeling TGD include two-dimensional finite element analysis and simplified sliding-block analysis. Representative models are illustrated in Figure C2.15. Finite element methods are complicated by the uncertainty associated with modeling slip along the soil failure plane and, in some cases, the need to account for separation at the boundary between stiff and soft soils. Sliding-block analogies face similar impediments with respect to defining a limiting value of shear strength for the soft soil and the sliding friction associated with the decoupled soil mass. Both methods require an explicit input ground motion time history that adds an additional layer of uncertainty in the modeling process.

At this time (2001), assessment of TGD remains a research topic. Unless there is compelling evidence to suspect that TGD displacements exceed a few centimeters, consideration of TGD is believed to be unnecessary for new pipelines or pipelines constructed in a manner consistent with modern construction. This position is supported by the fact that there is no evidence that TGD has been a factor in damage to such pipelines.

Older pipelines with potential weld or corrosion defects or not constructed with butt-welded pipe joints are at greater risk of damage from TGD. Given the lack of an accepted method for estimating TGD displacements, it does not seem prudent to devote large resources to estimating TGD for potentially susceptible pipelines. Instead, TGD damage occurring at unknown locations should be recognized as a possible consequence of the earthquake, and the need to potentially respond to TGD damage should be incorporated into earthquake response plans.

Type of Deposit	General Distribution of Cohesionless Sediments in Deposits	Likelihood that Cohesionless Sediments (saturated) would be Susceptible to Liquefaction (by age of deposit)

C3.0 PIPELINE PERFORMANCE CRITERIA

Determining limiting pipeline strains associated with varying levels of performance is an ongoing area of investigation within the pipeline industry. While there have been several notable projects using full-scale tests and detailed finite element analyses, the differences in load conditions, measurement techniques, and project goals make direct comparison difficult. As a result, defining appropriate relationships for seismic assessment of pipeline response is largely based upon available test data reported in the open literature and the collective judgment of the authors and reviewers contributing to these guidelines.

C3.1 New Pipelines and Pipelines Compatible with Current Construction Practice

There is experience in the pipeline industry of strain based design. Most of this is generally related to offshore applications such as pipe reeling for installation, high temperature, high pressure pipelines that can buckle due to high axial loading, and deepwater pipelines. Much of this experience relates to "load-controlled" situations on small diameter, low *D/t* (diameter to wall thickness), thick-walled pipes. In these situations, there is a high likelihood that the pipe will experience the design strain (in the range of 2% nominal strain[1]), thus validating the methodologies used. However, the strains in these applications may not be as large as those expected for seismic design. There are situations where pipelines have survived much larger strains, as well as instances where pipelines have failed at much lower strains.

The selection and specification of both pipe and welding for a strain-based design pipeline system includes consideration of a number of factors that may not be adequately addressed in a conventional stress-based design, which is thoroughly addressed in various codes and standards such as ASME B31.4, B31.8 and API 1104. Considerable research efforts in the pipeline industry have been directed at understanding the behavior of pipe at high strains, with this effort increasing over the last few years with more focus on strain-based design. Although the industry now has a vastly improved understanding of high strain behavior, significant advancements continue to be made.

The overall strain capacity of a pipe is dependent upon a number of factors:

1. ***Compressive Strain***:
    a. The properties of the pipe material including the shape of the stress-strain curve, the ratio of yield strength to tensile strength (Y/T), and uniform elongation strain (ε_{UL});

[1] Nominal strain is the strain that the pipe "globally" experiences over a certain gauge length (anywhere between 0.5 to 2 diameters). However, locally the strains can be much higher due to small geometric imperfections, and once a pipe starts to wrinkle and locally buckle, the strains that can be experienced in the vicinity of the buckle can be many times that of the nominal strain.

b. The *D/t* ratio, with a greater wall thickness having a higher strain capacity for the same pipe diameter (lower *D/t* ratio); and

c. Geometric anomalies associated with out of roundness (ovality) and wall thickness variations need to be considered for single pipe joints and at girth welds, where they can introduce wall thickness step changes when joints are butted together. The effect of geometric anomalies is to reduce the strain to initiate pipe wall buckling.

2. ***Tensile Strain:*** The tensile strain capacity depends upon the pipe material properties mentioned above, as well as the following factors related to the resistance of girth welds to the presence of welding defects:

a. Increased wall thickness reduce the effects of a loss of cross-section from weld defects and increases the amount of material available to resist crack growth;

b. Weld properties (yield strength, ultimate strength, and toughness) that meet or exceed the pipe metal reduce the potential for flaw growth; and

c. Weld quality specifications and inspection requirements increase the likelihood that girth welds will achieve the required properties and defect tolerances.

Key aspects of the above issues are briefly discussed below:

Pipe Steel Properties: The pipe properties of interest for both compressive and tensile strain capacities are the longitudinal properties. Circumferential properties are typically only of interest for assuring that the material is not anisotropic.

1. The stress-strain curve should be monotonically increasing, and should contain no plateau regions in the post yield portion of the curve. A high yield strength for the grade is not necessarily a benefit in strain-based assessments. It is good practice to obtain several stress-strain curves from the mill from full thickness, longitudinal specimens for the pipe.

2. The Y/T and ε_{UL} influence strain capacity with increases in strain capacity generally obtained by lower Y/T and higher ε_{UL}. Both of these values vary with pipe grade and the pipe toughness with increases in the grade and toughness generally resulting in higher Y/T ratios and lower ε_{UL} and lower strain capacities (i.e., X65 will generally have a higher strain capacity than X80). The required value of Y/T and ε_{UL} depends upon each application and the required strain capacity. Values of Y/T and ε_{UL} quoted in pipe material specifications need to be considered carefully, as "standard" values used in conventional specifications may not be sufficient. Specifying unusually low values of Y/T and high values of ε_{UL} may significantly increase costs for manufacturing the

limited amount of pipe that might be needed for seismic design and result in additional costs for testing to show that the pipe meets specifications. Some pipeline projects have taken steps to segregate pipe by heat and, therefore, Y/T properties. They then use the high Y/T pipe at high strain areas.

3. Weld heat affected zone (HAZ) properties are an important consideration as there is a tendency of certain low alloy materials to soften in the HAZ. This softening reduces the original pipe yield strength near the weld, leaving stronger material on either side of the zone. Once yielding occurs in the HAZ, all of the plastic strain will accumulate in this narrow zone, rapidly exhausting the available ductility and leading to plastic instability. Careful specification of the carbon level and the presence of secondary hardening alloys in the pipe steel is necessary to minimize the potential for softening in the HAZ.

Pipe Geometric Properties:

1. Wall thickness considerations include both the absolute thickness and variability. A thicker pipe wall increases both tension and compression strain capacities. This results in an additional benefit from using lower grade pipe as a lower grade pipe will require a thicker pipe wall. For example, if X65 is used for seismic design instead of X80, the strain capacity is increased because of both the lower grade (lower Y/T and higher ε_{UL}) and thicker wall (lower D/t). Careful consideration needs to be given to the allowable wall thickness tolerances in the pipe specifications as geometric misalignment decreases the compression strain for initiation of wrinkling (a concern for strain levels associated with continued operation). There is a trade-off between minimizing the geometric misalignment across the girth weld and the extra cost associated with having tighter tolerances.

2. Control of tolerances on pipe ovality, like control of pipe wall thickness, is important because ovality can reduce the compression strain for initiation of pipe wrinkling in a pipe joint. Furthermore, ovality of the ends of the pipe can result in geometric misalignment of the pipe ends at the girth weld that reduces the compression strain for initiation of pipe wrinkling in the same way as wall thickness variation. There is also a trade-off between minimizing pipe ovality and the extra cost associated with having tighter tolerances.

Welding Materials and Procedures: The presence of small imperfections or flaws in the weld deposit, and particularly those having a planar geometry and located near the root or cap of the weld, severely degrade the ability of the material to uniformly distribute plastic strain. Flaw extension in either a brittle or ductile mode from continuing strain at the extremities of these flaws leads rapidly to rupture. Because the imperfections cannot be entirely eliminated, a weld metal having slightly overmatching yield strength should be selected to minimize the opportunity for over-strain of the surrounding material. The degree to which the weld metal will overmatch the pipe metal must account for the possibility that the actual pipe strength may be significantly greater than the specified

minimum values. The need to achieve overmatching weld strength is another reason to consider the use of lower grade pipe steels in designing the pipeline to resist ground movement. A welding process should be chosen to minimize both the number and size of the imperfections. In the absence of highly skilled manual pipeline welders, the welding procedure should consider the use of mechanized GMAW or TIG processes.

Quality Control Over the Welding Process: The experienced-based workmanship requirements (flaw acceptance criteria) contained in the stress-based welding codes such as API 1104 or ISO 13847 may not be adequate for strain-based designs. New acceptance limits (generally smaller and fewer allowable flaw sizes) may need to be calculated based upon fracture mechanics technology. The fracture mechanics calculations used to determine weld acceptance are semi-empirical and require estimates of several parameters, particularly those related to flaw geometry, flaw location, material strength, and material toughness. Unlike approaches aimed at fitness-for-purpose assessments, the approach in these guidelines will not generally require the same high level of reliability that the pipeline will be capable of withstanding a particular tension strain for the reasons noted in Section C3.1.2. The level of required reliability needs to be considered when making decisions on the appropriate level of conservatism associated with the many assumptions necessary to establishing strain limits using fracture-mechanics approaches.

The new and smaller allowable flaw size presupposes that there will be an inspection system in place capable of detecting and sizing any flaws remaining in the weld. It is well established that flaw height and the distance to the pipe surface are the critical parameters. Conventional radiographic techniques are not suitable for either of these measurements and the use of a mechanized ultrasonic procedure such as that commonly used for offshore lay barges is recommended. Accuracies of about 0.040 inches are achievable for flaw height measurement in pipe with wall thickness less than about one inch. The net effect of the special welding procedure and the extensive post-weld inspection may lead to a high weld rejection rate, thereby reducing productivity and increasing cost per weld. However, this should be economically practicable considering the relatively few segments of the pipeline where seismically induced permanent ground displacements may occur.

Achieving strain limits as high as 2% to 4% may not be possible under certain circumstances, particularly for the assessment of existing pipelines with flaws or defects or where the use of high-grade pipe steel reduces the likelihood that girth welds will have strength and toughness characteristics superior to the pipe steel such that welds develop the full strength and strain capacity of the pipe steel. Specific criteria for assessing the strain capacity of girth welds is beyond the scope of these guidelines but techniques for performing such assessments are well-established. Two of the more common approaches to qualify pipe material and welding specifications for a specific project application depend upon either curved wide plate testing of weld specimens that conform to project specifications or theoretical fracture mechanics models.

It is noted that there may be additional proprietary data that would lead to an alternate basis for establishing pipeline strain acceptance criteria. Users of these guidelines may elect to review such additional data prior to establishing strain criteria for specific projects. As noted in Section C1.2, users that need to demonstrate levels of seismic reliability significantly higher than has been accepted in typical practice will likely need to adopt more conservative strain acceptance criteria than provided in these guidelines.

□□□□□□ □□r□r□ □□□□G□□□□M□□□□□□□r□□□□r□□□□□□r□□□

Failure in a strain-based design is normally taken to mean loss of the pressure boundary integrity. The failure can result from axial tensile overload or excessive bending. Bending involves both tension and compression strains with failure frequently occurring on the compression side of the bend as a result of a buckle in the pipe wall followed by a wrinkle. This leads to gross tension strain in local areas of the wrinkle. Most failures involve first the initiation of a partial thickness crack followed by brittle or ductile crack propagation through the wall. The latter may also involve out-of-plane ductile tearing.

Longitudinal Compression Strain Limit

In compression, local instabilities such as wrinkling can develop at strains much less than the allowable tension strain limits. Wrinkling of the pipeline wall does not, in itself, constitute a failure condition. While wrinkling may also lead to a significant reduction in pipeline moment capacity, this is not a concern for displacement-controlled conditions, as the pipeline deformation is not related to an applied load.

Under sustained loading conditions, further compressive shortening would be expected to concentrate at points of initial wrinkling. Typically, the initiation of compressive wrinkling occurs in the range of 0.3% to 0.6% strain for most large diameter pipes, or about one-tenth the strain level noted above for tension. Loss of pressure boundary integrity is associated with strains far greater than that associated with the initiation of compressive wrinkling for moderate *D/t* ranges.

In recommending longitudinal compression strain limits, the clear evidence of substantial compression strain capacity prior to rupture was tempered by the concerns regarding establishing recommendations on the maximum compression strain capacity that are much greater than past practice for seismic load applications within the pipeline industry (e.g., ASCE, 1984). The following discussion describes some of the test data used in assessing the suitability of equation (3-1).

Pipe tests performed by Mohareb et al. (1994) focused on conditions where the axial load was constant (five of the seven analysis cases utilized constant axial load). The axial force applied in the pipe tests by Mohareb et al. corresponded to a 45°C temperature differential, a tension force equivalent to the force necessary to counteract axial shortening from the Poisson effect of internal pressure, and a compressive force to counteract the tension produced by the closed-end conditions of the test specimens.

Ghodsi et al. (1994) repeated the tests of Mohareb et al., but include a girth weld in the center of the test specimen to assess the impact of a girth weld on initiation of wrinkling. The testing performed by Ghodsi et al. demonstrated that the presence of a girth weld significantly reduces the strain associated with a visual indication of pipe wrinkling. However, the reduction in the strain that could be reached in the tests was not as significant as the reduction in strain at initiation of wrinkling.

Pipe tests at the Center for Engineering Research (C-FER) in Edmonton, Alberta, Canada, have also been performed to examine post-wrinkling behavior. The details of the tests are proprietary but some results, including a relationships for compression strain limits for X70 steel, have been published by Zimmerman et al. (1995). The Zimmerman et al. relationship is reportedly based upon limiting maximum computed tension strain in the crest of the buckle formed after wrinkling to 10%.

Another testing program at the University of Alberta was carried out to investigate strains associated with the initiation of wrinkling (Dorey et al., 2001). These tests were performed on X70 pipe with a *D/t* ratio of 92 and internal pressures producing hoop stresses ranging from 0% to 80% of the specified minimum yield stress. These tests are relevant for comparing with equation (3-1) since they were taken past the point of wrinkle formation and development of maximum pipe moment capacity. Dorey et al. recommend several relationships for estimating the longitudinal strain in the pipe at the point of maximum moment. These relationships account for imperfections in the pipe wall and at the girth weld and also consider two typical shapes for the stress-strain curve of the pipe material.

Data from the available papers and test reports for the above tests are plotted in Figure C3.1 with strains associated with the end of testing plotted in Figure C3.1(a) and strains associated with initial wrinkling or maximum moment plotted in Figure C3.1(b). Several data points are plotted for the same *D/t* ratios. These data points correspond to different levels of internal pressure and net axial load applied during the testing. Internal pressure in the tests varies from zero to an internal pressure that produces hoop tensile stresses equal to 72% (Mohareb et al., 1994 and Ghodsi et al., 1994) or 80% (Zimmerman et al., 1995 and Dorey et al., 2001) of the pipe yield stress. Higher strains for the same *D/t* ratios are from tests with higher internal pressure.

The potential conservatism in equation (3-1) is clearly evident in Figure C3.1(a) by the fact that the maximum local compression strains imposed by laboratory tests with moderate to high internal pressure are typically at least two times greater than those given by equation (3-1). The only exceptions to this are the C-FER data. The smaller strains for the C-FER data may be a result of the presentation of limited data in the public-domain paper, the lack of interest in testing well beyond maximum moment, or the physical limitations of the testing configuration. It should be noted that all of the tests used to generate the data in Figure C3.1 were carried out without the pipe losing pressure integrity; hence, the actual safety margin against loss of pressure integrity is indeterminate.

Longitudinal Tension Strain Limit

Determining an appropriate tension strain limit will vary with welding specifications and inspection criteria and needs to be done on a project-by-project basis. The likelihood of achieving a particular strain capacity need not be unnecessarily restrictive. It is the intent of these guidelines that any acceptable strain criteria used on a particular project should be based upon the concepts of achieving a balanced seismic design as discussed in Appendix A. Estimates of the probability of pipeline failure at the specified strain limits in the range of 10% to 30% are judged acceptable for achieving a balanced seismic design in these guidelines. This level of weld failure, which may seem high compared to other applications such as fitness for purpose assessments, is justified in these guidelines where the likelihood of seismic hazard is the same as the acceptable likelihood experiencing seismic damage. Other factors supporting a higher acceptable probability of a weld not meeting a particular strain level are related to the low probability of a severe undetected flaw at a location of high strain.

It is expected that the allowable longitudinal tension strains will range from 2% to 4% for pressure integrity when evaluating pipeline response to permanent ground deformation. Longitudinal tensile strains of 3% to 5% have been adopted for assessing the ability of pipelines to maintain pressure integrity when subjected to earthquake-generated ground displacement for more than 20 years and are recommended in ASCE (1984). Advancements have been made in the use of fracture-mechanics approaches to estimate failure strains and the comparatively low strain capacities that often resul from fracture-mechanics approaches have raised questions regarding the suitability of historically adopted strain limits.

The magnitude of permissible computed tension or compression strain is limited to no greater than 4% based upon what is believed to be the practical limits of the ability of the analytical approach recommended in these guidelines to adequately represent pipeline behavior. Strain limits supported by additional test data, more refined analysis methods, or corroboration of the analysis approach with test or case history data are generally preferred.

Resolving differences between historic practice, test data, and fracture-mechanics approaches is complicated by several factors. Typical fracture-mechanics approaches were originally developed for applications that require a very low likelihood of failure. This low failure probability is achieved, in part, by adopting conservative assumptions with respect to the type of flaw, the location of the flaw, material toughness, and degree of weld overmatching. Thus, the strain estimates obtained by existing fracture mechanics methods are likely to be associated with a probability of failure much lower than required by the approach adopted for defining seismic hazards in these guidelines. Revising fracture-mechanics approaches to adequately match test data for strain capacities much greater than 1% and provide a statistical estimate of strain capacity is an area of active research within the pipeline industry.

The need to justify high strain capacities will vary among projects and the nature of the seismic hazards faced. In some cases, the required strain capacity necessary to withstand earthquake-generated ground movement is much less than 2% to 4% range recommended in these guidelines as generally achievable. There are also cases, particularly for high-cost projects, when a substantial increase in pipeline wall thickness required by adopting conservative fracture-mechanics based estimates of tension strain capacity may not have an economically significant impact, considering the increased wall thickness is only required at locations where earthquake ground movement is expected. Finally, ground displacements that are much more likely to occur compared to earthquake-related ground movement (e.g., frost heave, thaw settlement, active landslides, mining subsidence), generally require more conservative estimates of strain capacity to meet desired performance goals. For such cases, guidance on longitudinal strain limits is provided in Tables C3.1 through C3.3 based upon a fracture mechanics study by EMC^2 (Wang, 2003). The three tables provide three levels of longitudinal tension strain limits based upon material toughness and Y/T ratio. Comparison with test results described in the EMC^2 report indicate the tension strain limits in Tables C3.1 through C3.3 may have a mean factor of safety as high as 1.8 on strain. Users should carefully review the EMC^2 report to fully understand the basis for the recommendations in Tables C3.1 through C3.3 before adopting them for a particular project.

□□□□2□ □□r□r□ □□□□□G□□□□M□□□□□□□□□r□ □□□□ □□r□□□□□□

The compression strain limits to maintain normal operability for displacement-controlled conditions are largely based upon judgment. The magnitude of longitudinal tension and compression strains are limited to 2%. The reasons for the 2% limit are related to concerns about the overall distortion of the pipe cross-section that might be associated with coating damage or impair the passage of internal pigs.

Longitudinal Compression Strain Limits

Longitudinal compression strains associated with buckling instability of the pipe wall are limited to the value estimated using the maximum moment expression developed by Dorey et al. (2001). Although there is evidence that strains greater than those corresponding to the maximum moment onset of wrinkling can be sustained without appreciable deformation of the pipe cross-section, a conservative approach is adopted to reduce the likelihood of conditions that might impair the long-term integrity of the pipeline. Equations (3-3a) and (3-3b) are the equations developed by Dorey et al. (2001) for offsets at the girth weld. The compression strain limit from equation (3-3a) is plotted in Figure C3.1(b) for the case of X70 pipe with a p/p_y ratio of 0.72 and a Δ/t ratio of 0.10. Also plotted in Figure C3.1(b) are the pressurized test data points corresponding to initiation of wrinkling and maximum moment from tests performed at the University of Alberta. For comparison, data assembled by Stephens et al. (1991) from a wide variety of unpressurized pipe tests are also shown to illustrate similarity with the University of Alberta results. As shown by Figure C3.1(b), the 2% limit on strains for continued

operation governs for the conditions selected at *D/t* ratios less than about 57. The reasons for the 2% limit are related to concerns about the overall distortion of the pipe cross-section that might be associated with maintaining corrosion coating integrity or impair the passage of internal pigs.

Longitudinal Tension Strain Limits

Similar to the selection of tension strain limits for pressure integrity, the longitudinal tension strain limit associated with continued operation are associated with strains that can be accommodated without degrading corrosion coating or internal pig passage. The literature review for these guidelines did not identify information in the open literature relating the impact of longitudinal tension strain on the long-term integrity of the pipeline. Longitudinal tension strains of approximately 1% to 2% seem to be reasonable considering that these strains are generally less than what might be generated during field cold bending operations. Lacking additional information or project-specific test data, it is suggested that longitudinal tension strains for continued operation be taken as half of the tension strain limits for pressure integrity.

[illegible]

The loading conditions considered in these guidelines are typically governed by imposed displacement of the surrounding soil (displacement-controlled). There are some situations where the pipeline loads may not be related to displacement (load-controlled). In the ASME codes, load-controlled conditions are considered primary loads and displacement-controlled conditions are considered secondary loads. Seismic inertial loads are an example of primary loads for aboveground piping.

Examples of load-controlled conditions include flow-type ground failures and situations where ground failure removes soil restraint around a section of pipeline. Figure C3.2 illustrates pipeline configurations corresponding to these two ground displacement conditions. Other examples of load-controlled pipeline conditions not related to earthquake hazards can be found in the offshore industry where pipe laying operations can impose strains in the pipe that must be accommodated without degradation in pipeline strength. For load-controlled situations, local buckling of the pipeline can lead to progressive deformation and pipeline rupture.

In developing load-controlled strain criteria, consideration was given to establishing a uniform strain limit of 0.005, the strain at which the specified minimum yield strength is determined. For most pipeline steels historically used for gas transmission pipelines, stresses below the specified minimum yield stress (corresponding to a strain of 0.5%) do not pose a significant risk for progressive deformation. However, for compression strains, this limitation underestimates strain capacities for pipes with low *D/t* ratios and may underestimate strain capacity for pipes with very high *D/t* ratios. It is also desirable to account for the beneficial effects of internal pressure in reducing the loss of bending strength of the pipe once the maximum moment is reached. The approach adopted is to

base the compression strain limits on the maximum moment relationships developed by Dorey et al. (2001) that are recommended for continued operation. For load-controlled conditions, the relationships developed by Dorey et al. (2001) are factored by 0.75 to provide a reasonable margin against exceeding the maximum moment. The Stephens et al. (1991) relationship is used as a lower limit for compression strains under load-controlled conditions as this relationship represents a 95% lower bound fit to a large database of tests on unpressurized pipes assembled by Battelle.

C3.2 Considerations for Offshore Pipelines

The strain criteria for offshore pipelines undergoing bending and external pressure is adopted from the approach of Murphey and Langner (1985). This approach was adopted because of the relatively simple forms of the governing equations. Alternate approaches such as BS 8010 or API Bulletin 5C3 were also considered. Alternate approaches can be used but the degree of variation in the resulting allowable bending strains are well within the expected variation in hazard quantification.

Tension in offshore pipelines reduces the estimated collapse pressure by reducing the hoop stress at which yielding occurs. The approach adopted in these guidelines is consistent with past recommendations (AGA, 1990) as well as recent investigations (Foeken and Gresnigt, 1998). The approach limits the effective von Mises stress to the material yield stress. For a particular value of axial stress, the hoop stress corresponding to a von Mises yield condition is estimated as follows:

$$\sigma_{yh-red} = \sigma_{yh}\left[\sqrt{1-\frac{3\sigma_a^2}{4\sigma_{yh}^2}}-\frac{\sigma_a}{2\sigma_{ya}}\right] \qquad \text{(C3-3)}$$

where:

$\sigma_{yh\text{-}red}$ = reduced hoop yield stress

σ_{yh} = hoop yield stress

σ_{ah} = axial yield stress

σ_a = applied axial stress

With the simplifying assumption that the axial and hoop yield stresses are equal to the nominal yield stress, σ_y, equation (C3.3) limits the tension strain limit to less than the yield strain.

C3.3 Pipelines Not Compatible with Current Construction Practices

Pipelines not covered by the strain limits in these guidelines include pipelines with one or more of the following characteristics:

1. Alternate girth weld details
2. Welds with detectable crack defects or not acceptable by current welding criteria
3. Corrosion defects
4. Undermatched welds

Pipelines with Alternate Connections Details

Older pipelines may have been constructed with welded slip joints, bell-bell-chill-rings, or other non-butt-welded pipe joints. In addition, pipelines may have been fabricated with mechanical connections such as Dresser® or Victaulic® couplings. The specific details of the configuration of these joints can significantly reduce their strain capacity. For example, depending upon the shape of the bell for welded slip joints, local buckling under longitudinal compression may occur at strains well below the yield strain of the pipe (Tawfik and O'Rourke, 1985). The vulnerability of older pipelines with non-butt-welded pipe joints is often compounded by the fact that the quality of the welds is typically much worse than obtained by more recent construction practices.

It is not possible to define generic recommendations for establishing strain limits for non-butt-welded pipe joints. Detailed finite element analyses utilizing shell elements capable of capturing the effects of material yielding and local wall buckling is perhaps the most cost-effective approach to assess strain capacity for non-standard girth welds. If the welds are suspected of having defects, the finite element analyses will need to be combined with fracture mechanics-based assessment of strain capacity for the defective weld.

Pipelines with Corrosion or Weld Defects

Evaluating the effects of corrosion or weld defects is a potential issue for the assessment of existing pipelines. Explicit consideration of the effect of defects is limited to cases where evidence from past pipeline repairs or findings from internal inspections permit quantification of defect size and distribution. Assessing pipelines for weld and corrosion defects requires expertise in fracture mechanics and experience in characterizing defect geometry and material toughness parameters. Test data on pipe or weld toughness properties are normally not available for existing pipelines. The lack of data generally leads to removing samples of material for testing, fabrication of simulated test specimens, or estimating parameters based upon correlations with similar pipe material, chemical composition, or Charpy test data.

Procedures for estimating the strain capacity of pipelines with weld or corrosion defects is an area of ongoing research. Much of the work is related to estimating to what extent defects, in combination with relatively small amounts of induced bending, reduce the safe pipeline operating pressure. For seismic assessment purposes, the more common situation is longitudinal strains exceeding yield from axial or bending response with the pipeline operated well below its maximum permissible pressure.

There are many references that can be consulted regarding the assessment of weld and corrosion defects and non-standard joint details. Examples include ASME B31G (ASME, 1991), Roberts and Pick (1998), Rosenfeld (1996), Wang et al. (1996, 1998), Wang (2003), Warke and Amend (1997), and Warke et al. (1997).

For the majority of older pipelines, available information is often limited to pipe size, wall thickness, and material specification. In some cases, there may be coupon tensile test data but this is typically from a statistically insignificant number of pipe samples. This lack of data can severely limit the analytic tools available to estimate strain capacity. In many cases, a decision will need to be made as to whether or not it is necessary to take a pipeline out of service to remove test samples for determining mechanical properties. Information gathered from the operational history of the pipeline, limited excavation to examine the pipeline, information from field personnel on site during construction of the pipeline, and historical experience with the performance of pipe suppliers and pipeline contractors can provide sufficient information to form a judgment on the strain capacity of a pipeline suspected of having weld or corrosion defects. Extraction of specimens for testing is typically limited to cases where potential pipeline damage from a seismic hazard is judged to be extremely serious.

It is not necessary to establish a very conservative acceptable strain limit for the purposes of the seismic assessment. The typical approach to determining an acceptable strain limit for pipelines with weld or corrosion defects is to assume that the defect is located on the circumference coincident with the occurrence of maximum pipe strain. This approach can be very conservative. The combination of maximum pipe strain with a defect is dependent upon the variation in location of of ground displacement, the direction of ground displacement with respect to the pipeline alignment, and the variation in the distribution of weld defects around the circumference or the distribution of corrosion defects around the circumference and along the pipeline. It should be remembered that the approach described in these guidelines is assumed to contain sufficient conservatism in the definition of the seismic hazard. If highly conservative approaches to assess the impact of defects are applied, it is reasonable to consider reducing the conservatism in defining the seismic hazard.

Pipelines with Undermatched Girth Welds

For the purposes of these guidelines, girth welds are considered to undermatch the pipeline material if the actual weld metal yield strength and toughness do not exceed the actual values of yield strength and toughness of the pipe material. There is considerable

evidence (e.g., Denys, 1992, 1993, 1994; Horsely et al., 1997) that undermatching girth welds prevent the development of gross-section yielding generally assumed to occur in the analysis of pipeline response to permanent ground displacement. If weld undermatching is suspected, tension strains for pipeline assessment should be based upon limiting pipe stresses to the yield stress of the weld unless data are available to support higher values.

Studies investigating the effect of weld undermatching on compression strains have not been identified. It seems reasonable to assume that the effect of undermatched girth welds is much less under compressive loading. Unless there is reason to believe that local yielding of the weld metal substantially reduces the occurrence of local buckling of the pipe wall, it is recommended that no adjustment is necessary to the longitudinal compression strain limits for undermatched girth welds.

It must be pointed out that undermatched welds are rare for most existing pipelines and the majority of new pipelines. Weld undermatching has only become a significant concern with the recent introduction of high-strength pipelines steels consistent with API 5L Grade X70 and above. However, without careful weld specifications, it is possible to have undermatched welds for lower strength pipe. The difficulty in achieving weld overmatching may limit the ability of higher grade pipe steels from being used when it is necessary to resist significant seismic ground movements.

Assessing the Risk of Not Meeting Performance Goals

The ability of the pipeline to achieve the desired level of performance, expressed as an annual probability estimate, should be taken as the product of the annual probability that the pipeline will experience ground displacements greater than the capacity assuming factored strain limits and the probability that the pipe defects more severe than those accounted for exist in portions of the pipeline experiencing high strain levels. This can be expressed analytically in the following manner:

$$P_G = P_{GD}\left[1-\left(1-P_D\right)^n\right] \qquad \text{(C3-2)}$$

where:

P_G = computed performance expressed as an annual probability of exceedance

P_{GD} = annual probability of exceedance for the earthquake producing the ground displacement hazard representing the pipeline capacity with reduced strain limits

P_D = probability that the reduced strain limit for any individual weld is less than expected accounting for the variability in defect distribution and methods for relating defect size to strain capacity

n = number of welds exposed to strains above the reduced strain limits

As an example, consider the following conditions:

> Analysis of a portion of a pipeline assuming nominal properties indicates that a pipeline subjected to permanent ground movement is adequate to meet the desired performance goal, defined as an annual probability of loss of pressure integrity no greater than 0.2%. The ground displacement corresponding to a 0.2% annual probability of exceedance is 2 m (6.6 ft) and is governed by longitudinal tension strain. Inspections of another portion of the pipeline built at the same time and by the same contractor indicate a potential for girth weld or corrosion defects. A reduced longitudinal tension strain capacity is determined based upon the most severe flaws identified by the prior inspection and fracture mechanics analyses. It is estimated that there is a 5% chance that the actual reduced strain capacity will be less than the determined reduced strain limit for any one weld. The reduced longitudinal tension strain capacity is exceeded for ground displacements greater than 1.25 m (4.1 ft). The analysis of pipeline response indicates that the length of pipeline exceeding the reduced strain limits is approximately 120 m at the full ground displacement of 2 m. The annual probability of exceeding 1.25 m of ground displacement is estimated to be 0.5%. The pipeline was constructed with 12-m (40-ft) joints of pipe.

The annual probability of loss of pressure integrity accounting for the potential for defects is estimated as follows:

$P_{GD} = 0.005$

$P_D = 0.05$

n = 120 m ÷ 12 m/joint = 10 girth welds

$$P_G = 0.005\left[1-(1-0.05)^{10}\right] = 0.002$$

The pipeline with defects can be considered as meeting the performance goal since the estimated probability of exceeding the reduced strain limit is equal to the 0.2% defined by the performance goal. While the annual probabilities of exceeding acceptable longitudinal tension strain limits are the same, the probabilities associated with a particular time interval can be different.

For a 50-year time frame, T, the probability of ground movement exceeding 2 m (i.e., not meeting the desired performance goal) is computed as follows:

$$P_{eT} = \left[1-(1-P_e)^T\right] = \left[1-(1-.002)^{50}\right] = 0.0952$$

where:

P_{eT} = probability of exceeding nominal strain limit in time T

P_e = annual probability of earthquake more severe than defined by the performance goal

T = time frame for computing P_{eT}

The above calculation may greatly overestimate the likelihood of failure in 50 years because it assumes that the pipeline has a 100% probability of failure at the strains produced by a 2-m ground displacement.

The probability that the reduced longitudinal tension strain will be exceeded in the same 50-year time frame is computed as follows:

$$P_{erT} = \left[1-\left(1-P_{GD}\right)^{T}\right]\left[1-\left(1-P_{D}\right)^{n}\right]$$
$$= \left[1-\left(1-.005\right)^{50}\right]\left[1-\left(1-.05\right)^{10}\right]$$
$$= \left[0.2217\right]\left[0.4013\right] = 0.0890$$

where:

P_{erT} = probability of exceeding reduced strain limit in time T

T = time frame for computing P_{erT}

The differences in the above example probability calculations are not significant considering the level of uncertainty in estimating earthquake hazards. This is generally the case when the pipe meets the desired performance goal considering the effects of potential defects in a probabilistic manner. When it is useful to express the probability in terms of a reference time frame, basing calculations on only the annual probability of exceeding acceptable longitudinal strain capacity is generally sufficient.

C4.0 PIPELINE ANALYSIS PROCEDURES

Experience in the oil and gas industry with respect to the analytical evaluation of buried pipeline response to large permanent ground deformation dates back to the mid-1970s. This experience includes simple evaluation methodologies as well as more sophisticated finite element approaches. A brief summary of this history and the experience of pipelines undergoing large ground deformations is presented as a means to introduce the discussion of analytical methods and results in these guidelines.

Differences in the relative stiffness between the pipe and the soil lead to relative pipe-soil movements. Large relative movement is an indication that the pipeline has considerably more strength than the surrounding soil at that particular location. Therefore, high-strength pipeline material is generally more beneficial in resisting highly localized soil deformation.

The geometry of the pipeline may allow for concentration of loading and relative displacement, leading to the development of locally large strains in the pipeline. Because these load conditions are produced by an imposed displacement, relatively large strains can be accepted provided the pipeline is in good condition and the girth welds are capable of developing gross-section yielding of the pipe. To accommodate the large strains, it is beneficial to have a ductile material (such as the steels considered in this evaluation) that hardens gradually between its yield and ultimate strength capacity. This allows for a more uniform distribution of strain and lessens the likelihood of local tearing of the pipe wall.

The first approach for estimating the response of buried pipelines to large ground deformations is generally credited to Newmark and Hall (1975). Their approach provided a means to quantify the amount of strain that could be accumulated in a buried pipeline crossing a fault. The basic components of the analysis are the stress-strain properties of the pipeline steel, the ground deformation geometry, and an estimate of the variation of the axial loading placed on the pipeline by the soil. The analysis assumed a straight pipeline configuration across a fault-like discontinuity.

A modification of the Newmark and Hall approach, developed by Kennedy et al. (1977), allowed the incorporation of bending effects into the analysis. The Kennedy et al. method accounted for bending by relating the lateral soil forces on the pipeline to an assumed amount of imposed pipeline curvature. The modified approach of Kennedy et al. is best suited for instances of large ground movement for which the bending strength of the pipeline, while significant, is not a dominant feature of the pipeline response. For small amounts of deformation where bending effects are significant, Kennedy et al. outlined the process for including a local bending analysis into their methodology. However, this process is cumbersome and is rarely considered practical compared to finite element methods.

Both the Newmark and Hall and Kennedy et al. approaches are practically limited to consideration of initially straight pipelines, single components of lateral offset (either vertical or horizontal), constant soil-pipeline interaction parameters and negligible pipe

bending stiffness. By the late 1970s, use of nonlinear finite element techniques were accepted as the preferred means to analyze all but the most simple of problems. Finite element approaches provide a means to rapidly investigate the effects of changes in backfill characteristics, pipeline material, wall thickness, and pipeline alignment. In addition, the assumptions used to formulate closed-form approaches like those of Newmark and Hall and Kennedy et al. have not been substantiated in comparison with finite element analyses as recommended in these guidelines.

The mechanics of implementing a finite element analysis have changed little in the last 15 to 20 years. The primary advancement in performing analyses has been in the availability of powerful desktop personal computers and compatible nonlinear analysis software that accounts for material yielding and large deformations.

The recommended analysis approach models the pipeline with beam-like elements capable of capturing nonlinear material behavior and the effect of large deformations. It is preferred that the analysis software include a pipe element in its element library with the capability to model internal pressure and provide output at various circumferential locations. These characteristics limit the amount of effort necessary to define pipe properties and the effort related to interpretation of the output from the analysis.

The recommended analysis approach can not account for localized straining that occurs once pipe wall buckling initiates. The recommended approach will underestimate local and global post-buckling strains in the region of the buckle. However, because of the displacement-controlled loading, and the fact that research into pipeline behavior has not, to date, been able to develop monotonically increasing strains of sufficient magnitude to produce rupture in a buckle (i.e., no rupture except by burst testing), this is considered acceptable. Also, refined calculations into the post-buckling region, based upon the use of nonlinear shell elements, have not yet been established to the point where they can be considered to be design tools.

C4.1 Pipe Element Definition

The one-half diameter limitation on the length of pipe elements in areas of high strain is related to the gauge length typical of full-scale pipeline tests. Shorter pipe elements promote the localization of plastic strains that have been observed in the tests.

Stress intensification and flexibility factors are based upon elastic pipeline response and are not applicable to analysis of nonlinear pipe behavior. The use of multiple straight pipe elements to represent bends and elbows introduces localization of strains that may be overly conservative considering the greater flexibility typical of elbows. However, the beneficial effect of elbow flexibility decreases with increasing *D/t* and internal pressure. Conservatism in the treatment of elbows is warranted because of the lack of sufficient tests to determine applicable strain limits for elbows. However, tests on Grade B elbows have demonstrated that they have the ability to withstand severe deformation while maintaining internal pressure integrity (Yoshizaki et al., 1998).

The use of sections of elbows cut to provide angle changes other than standard 90° or 45°. The wall thickness of elbow fittings is typically not uniform around the circumference will vary depending among different manufacturers. Because of these factors, sections of elbow fittings require special attention because of the potential for a significant mismatch in wall thickness between the pipe and the elbow section. This mismatch in wall thickness can lead to stress risers and reduce the strain capacity of the welded connection.

The length of the pipeline model should be sufficient to adequately capture the anchoring effects of the soil outside the zone of ground movement. Extending the pipeline model a considerable distance outside the zone of ground movement typically does not significantly lengthen the solution time for the analysis as the pipeline response is mostly elastic. In cases where a particular analysis program is impacted by an extended pipeline model, a shorter length can be used if analyses are performed to confirm that longer models do not appreciably change the maximum computed strains.

It is assumed that the pipeline analyses are performed using a multi-linear uniaxial stress-strain curve to represent the pipeline material. The procedure for defining the compressive stress-strain curve is an attempt to capture trends exhibited in full-scale pipe tests. Pipeline test results demonstrate an abrupt softening in the moment versus curvature behavior of unpressurized pipelines strained beyond the point of maximum moment capacity (Yoosef-Ghodsi et al., 1994, Mohareb et al. 1994, Zimmerman et al., 1995).

Not capturing the reduction in moment capacity that accompanies formation of a local buckle in the pipe wall is not a significant shortcoming. As discussed in Section C4.2, the representation of the soil loading does not account for the reduction in maximum soil load at large relative pipe-soil displacement. The use of a constant maximum soil load forces continued deformation of the pipeline once yielding is reached. Localization of bending strains is not a concern because the pipeline is limited to the displacement experienced by the surrounding soil.

C4.2 Pipe Stress-Strain Definition

(No additional commentary provided)

C4.3 Soil Spring Definition

Relative movement of the surrounding soil with respect to a buried structural element imparts loads on that element. The magnitude of these loads was initially investigated to understand the performance of footings, piles and soil anchors. In the early to late 1970s, several research programs developed soil loading relationships specifically for buried pipelines. A key characteristic of soil loading is that it increases only to the point at which gross failure of the soil occurs. For example, the maximum lateral load that can be imparted to a buried pipe is related to the load necessary to develop a failure plane in the

soil. Once this load has been reached, further relative displacement serves primarily to move soil along the failure plane.

The limited nature of soil loading on the pipeline is commonly represented in analytical approaches by modeling the soil with bilinear springs. This approach is conservative because forces necessary to carry soil along the established failure planes are typically less than those needed to initially generate the failure plane in the soil. An approximate analogy in mechanics is the relationship between static and sliding friction.

It is possible to estimate the reduction in soil loads for large relative displacements based upon soil mechanics analyses or test data. The analysis approach using beam-like pipe elements in the analysis of pipe response is not compatible with such soil loading representations because of the inability to capture the reduction in moment capacity at large pipe strains. If a more refined estimate of soil loading is used, the modeling of the pipe should be modified to capture the localized straining that occurs in the vicinity of a buckle in the pipe wall.

There is considerable uncertainty regarding the relationships used to compute soil spring properties. Most of this uncertainty is related to estimates of the soil strength parameters. The uncertainty in estimating soil strength parameters for pipeline analyses in cohesive soils is further complicated by the fact that pipelines are typically located above the water table and within the desiccation zone of the soil. The strength of partially saturated desiccated soils is not well defined in soil mechanics practice.

The equations provided for the parameters N_{qh}, N_{ch}, N_{qv} N_{cv}, and N_{γ} are developed from empirical curves found in the literature. The equations are particularly useful when implementing calculations in a spread sheet or computer program. The curves from which the equations were developed are provided in Figures C4.1 to C4.4.

Most of the soil loading relationships in these guidelines are nearly the same as those recommended by the Gas and Liquid Fuel Lifelines Committee of the ASCE Technical Council on Lifeline Earthquake Engineering (ASCE, 1984). One exception is the relationship for estimating axial soil loads in cohesive soils. These guidelines utilize the adhesion curve developed by Honegger (1999b).

There is considerable recent research supporting the use of the approach in these guidelines for estimating soil loads. Examples include centrifuge modeling tests (Paulin et al., 1995, 1996), field tests (Cappelletto et al., 1998, Honegger, 1999b, Rizkalla et al., 1996), and finite element analysis (Altaee et al., 1996). There is some evidence from laboratory tests that the lateral soil loads determined by the equations in these guidelines may overestimate the maximum soil loads (Paulin et al., 1998). However, this evidence is from an ongoing proprietary research program, and there are a number of technical issues relating to modeling similitude and load rate that require resolution. Until the findings from this proprietary research become available for review or other data are published from tests at seismic loading rates, the expressions contained in these guidelines represent the best approaches available. As an alternative, it is always permissible to utilize test data for a particular soil condition.

C4.4 Extent of Pipeline Model

(No additional commentary provided)

C4.5 Representation of Applied Ground Movement

The use of abrupt transition in the applied ground movement at faults and boundaries of lateral spreads and landslides is required in these guidelines unless site-specific information is available to justify other patterns. This is not an unrealistic assumption based upon the observation of abrupt transition patterns in past earthquakes. The assumption of an abrupt transition is conservative in that the computed strains are likely to be substantially greater than those computed assuming a more gradual transition. This approach is consistent with the representation of soil loading and analysis methods used in these guidelines. That is, the definition of ground deformation hazard, as represented by the soil loads and deformation pattern, is conservative while the assessment of pipeline response, represented by the strain criteria and pipeline modeling approaches, is believed to be more median-centered.

An alternate approach for expressing ground displacement based upon observations from Japanese earthquakes is to assume a pattern defined by a cosine function raised to the power of *n* as given in equations (C4-1) and (C4-2).

For slide-type displacements:

$$\begin{aligned} y(x) &= 1-\delta\left(\cos\frac{\pi x}{W_s}\right)^n && \text{for } \frac{x}{W_s}\le 0.5 \\ &= 1- \quad \delta\cdot\left(\cos\left[\pi\left(1-\frac{x}{W_s}\right)\right]\right)^n && \text{for } \frac{x}{W_s}> 0.5 \end{aligned} \tag{C4-1}$$

For fault-type displacements:

$$y(x) = 1-\delta\left(\cos\frac{\pi x}{2W_f}\right)^n \tag{C4-2}$$

where:

$y(x)$ = displacement as a function of location, x, within the zone of deformation

x = distance across the zone of deformation

H = rupture depth, km

δ = amount of displacement

W_s = width of slide zone

W_f = width of fault zone

The cosine functions given by equations (C4-1) and (C4-2) are graphed in Figure C4.5 for various powers of *n*.

A displacement pattern corresponding to an *n* of 10 is representative of slide and fault displacements. A more abrupt transition, approximated by an *n* value greater than 100 has also been observed in some earthquakes. Other displacement patterns established based upon historical observation or rational analysis may be used for characterizing ground movements.

Practically, current empirical or analytical methods for quantifying seismic ground movement hazards are also not capable of quantifying the behavior at boundaries. The most appropriate basis for estimating more gradual transitions in ground movement is historical evidence. This type of information is typically limited to areas of high seismic activity where a historical record of observed ground deformations exits. If the basis for a more gradual transition is judgment, the sensitivity analyses should include an abrupt transition in ground deformation pattern.

C4.6 Sensitivity Analyses

Sensitivity analyses are recommended to provide some indication of the sensitivity of computed pipeline strains to various input parameters. The primary reason for performing sensitivity analyses is to assess the impact of uncertainty regarding definition of the earthquake hazard and soil loading parameters.

The recommended variations in these guidelines are based upon the premise that the soil spring definitions in these guidelines tend to overestimate soil loads. Some determination of the expected variability in modeling parameters should be included in the scope of any assessment. While higher soil loads generally produce more severe pipeline distortion, there are certain exceptions. A simple example illustrates this point.

Consider a pipeline alignment shown in Figure C4.6 subjected to right-lateral strike-slip faulting. The pipeline has an induction bend west of the fault and a 90° 3R elbow on the east side of the fault approximately 350 m from the induction bend. Given the shallow crossing angle, the response of the pipeline is governed by axial loads between the two bend locations. With this configuration, the two bends have the potential to behave as anchors. Overestimating the axial soil loads on the pipeline will tend to focus high strains at the induction bend. As the pipeline strains axially, the soil loads gradually reduce and may be insignificant at the 3R elbow if the total axial strain is sufficient to allow no relative displacement at the elbow. If the soil loads are underestimated, the soil will tend to slide along a much greater length of pipeline because the strains induced by the low soil loads are not sufficient to match the ground displacement. In this case, the strains at the induction bend may be reduced but one leg of the 3R elbow will be forced by high lateral soil loads to match the difference between the ground displacement and

the axial pipe elongation. In effect, soil reaction forces developed at the 3R elbow will be pulling the pipe between the bends to accommodate the displacement mismatch. This condition can shift the most critical location of pipeline straining from the induction bend to the 3R elbow.

This example demonstrates that possible variations in soil spring definition can not only define the variability in computed strains but may also indicate a potential for alternate critically loaded portions of the pipeline alignment. When selecting variations of soil springs for sensitivity analyses, the potential for such behavior should be considered. This may involve a more extreme variation in soil spring definition and a separate assessment to determine the likelihood of experiencing such an extreme variation.

C5.0 MITIGATION OPTIONS

As with pipeline design and assessment guidelines, the benefits of implementing mitigation measures have generally not been demonstrated by experience in actual earthquakes or in controlled tests. A notable exception being the limited field testing performed to validate the concept of dual layers of geotextile wrapping. The presentation of mitigation options is limited to a general discussion of various techniques that have been implemented or considered in the past. For this reason, no additional discussion of potential mitigation options is provided in this commentary.

This Page Intentionally Left Blank

CONSIDERATIONS FOR ESTABLISHING PERFORMANCE GOALS

Existing pipeline standards emphasize minimum requirements for normal design, construction, and operation. Many pipeline companies exceed the requirements stipulated by the standards for safety and reliability. With regard to seismic hazard mitigation, the appropriate level of seismic design is typically determined on a project-by-project basis using site-specific information to define the seismic hazard exposure and the current state-of-practice. In practice, this often results in the definition of seismic performance goals for the pipeline being based largely upon criteria adopted from other non-pipeline projects, with similar consequences to the public.

A fundamental question to be answered in performing a seismic assessment for a new or existing pipeline is what level of performance is necessary. These guidelines assume a definition in terms of an annual probability of exceeding an unacceptable condition such as excessive pipe deformation or loss of pressure boundary integrity. This probability is then equated to the probability of occurrence of the earthquake.

A.1 Objectives

The main objective of seismic design for natural gas transmission and liquid hydrocarbon pipelines is to provide life/safety protection from the effects of stipulated design earthquakes distributed along the pipeline route. A secondary, but important, objective is to minimize capital loss and disruptions to operations.

The goal for seismic design of natural gas transmission and liquid hydrocarbon pipelines is to achieve a balanced design to withstand the effects of earthquakes and other loads which is both safe and economically feasible. The design should take into account the nature and importance of the project, cost implications, and risk assessment centering around such items as public safety, loss of product or service, and damage to property and the environment. The treatment of the seismic hazards should be consistent with the treatment of other natural and manmade hazards.

The concept of a balanced design may be difficult to achieve because many of the parameters necessary for making rational decisions are either unknown or not well defined. The goal of a balanced design is for all major components of a pipeline system to have failure risks and consequences that are consistent with system performance objectives. Pipelines and support facilities should be designed to withstand the effects of earthquake ground shaking and permanent ground movements that have a reasonable probability of occurrence along the route during their operational life.

A.2 Dual-Level versus Single-Level Earthquake Hazard Definition

The use of dual-level earthquake design criteria is an outgrowth of practices developed for the nuclear power industry and other projects (e.g., offshore structures) where seismic

damage has the potential for severe safety or environmental consequences. The origin of the two-level design earthquake was primarily intended for the design of buildings and surface structures, with their contained electrical and mechanical systems and aboveground piping systems. The first major pipeline project to adopt dual-level earthquake criteria was the Trans-Alaska pipeline, but design implementation was restricted primarily to aboveground pipeline segments.

Current practice for the seismic design of major pipeline facilities (new construction) often follows the precedent set for offshore oil production platforms, Department of Energy critical facilities, and nuclear power plants in that two levels of earthquake hazard are selected for design. In this approach, the low level event generally has a return period on the order of 200 to 500 years. The higher level event is generally one that has a return period on the order of 1,000 years or more, depending upon the nature of the facility.

The lower level event is often viewed as a threshold for continued operation of the pipeline within accepted safety margins and little if any permanent deformation of the pipeline is permitted. The pipeline response to higher level event is typically required to prevent a threat to safety, although significant structural damage could occur. Specific criteria for the response of the pipeline to these events, including the amount of permissible damage, varies according to the type of structure or component and its function. The selection of earthquake return periods and performance objectives should be established through a project-specific risk assessment.

There is no standard nomenclature for referring to the two earthquake levels. The lower level event is often referred to as the "probable design earthquake" (PDE), the “design basis earthquake” (DBE), or the “strength level earthquake” (SLE). The higher level event is commonly referred to as the "contingency design earthquake" (CDE), “maximum credible earthquake” (MCE), “safe shutdown earthquake” (SSE), or “ductility level earthquake” (DLE).

For the design or assessment of buried pipelines it is not clear whether a two-level design is necessary or practical in many cases. The fundamental difference in the condition expected of buried pipelines and typical structures and equipment following the low-level earthquake should be considered if a dual-level earthquake design is specified. Establishing a lower level earthquake for structures and equipment generally assures that the post-earthquake condition is essentially the same as the pre-earthquake condition for the less severe earthquake. This is expected because their primary earthquake loading condition is a transitory inertial excitation. However, the primary earthquake load on buried pipelines is permanent ground displacement. The pipeline’s total strain capacity to resist ground displacement in the future is reduced because of the strains produced by the low-level earthquake displacements. Also, it is possible that landslide and lateral spread hazards are not direct functions of the level of ground shaking necessary to trigger large displacements. These factors should be considered with respect to the purpose of specifying a dual-level earthquake to provide an increased likelihood of normal operation for moderate events and prevent loss of pressure integrity for major events.

The decision on whether or not to specify a dual-level earthquake design for a buried pipeline may also be influenced by considering measures that may be required following an earthquake that produces permanent ground displacement. Following the earthquake, a decision will be necessary regarding the suitability of the pipeline for continued short-term and long-term service. Considerations impacting this decision include the consequences if the pipeline performance is compromised by future ground displacement, the likelihood for future earthquake generated ground displacement during the life of the pipeline, the remaining capacity of the pipeline to withstand future ground displacement, and the consequences to customers if pipeline operations are interrupted.

Given that this decision process generally occurs regardless of the level of ground displacement experienced by the pipeline, it is not clear what benefits are to be gained by specifying two levels of earthquake hazard. This is especially true for cases where analysis provides information on pipe strains as a function of ground displacement such that the pipeline response for lower level events is understood.

Another consideration relates to the assessment of permanent ground displacement patterns after an earthquake when the ground displacement was insufficient to lead to loss of pipe contents. With the exception of well-defined abrupt surface expressions of displacement, it is often necessary to compare the positions of surface features following the earthquake that were known before the earthquake in order to evaluate the extent of ground deformation. Examples of such surface features include roads, sidewalks, fence lines, and survey monuments. In the case of pipelines within a liquefiable soil experiencing lateral spread movement, the problem is compounded by the fact that the ground movements within the liquefiable layer may not be well represented by surface ground displacement. In most earthquakes, detailed surveys are necessary to determine the amount of ground displacement. In remote locations, it is not unusual to have no pre-existing features from which to ascertain ground displacement. In such cases, assessment of pipeline condition is often qualitative and relies on limited excavation of the pipeline to observe any signs indicative of large strains (e.g., wrinkles, damaged coating, gaps between the soil and the pipe, ovaling of the pipe). It may also be decided to use an instrumented pigging device to identify any abnormalities in the pipe wall or alignment. In any case, assessing pipeline response to ground displacement following an earthquake may take several days or weeks.

These problems can be reduced somewhat by performing surveys to locate surface features or to install survey monuments prior to the earthquake in the vicinity of areas expected to experience ground displacement. Post-earthquake surveys using GPS equipment can then provide a relatively rapid assessment of the amount of ground displacement that has occurred in the vicinity of the pipeline. This entails some long-term costs for verifying the survey and maintaining survey monuments.

Whether a pipeline is to be constructed onshore or offshore may dictate the need to account for differences in the consequences of seismic damage when establishing performance goals. Seismic damage to an offshore pipeline would result in a more difficult repair situation than for an onshore pipeline, particularly in an extreme climate or deep water, or in cases where the pipeline is deeply buried to protect against anchor

dragging, ice gouging, etc. The increased difficulty is due mainly to mobilizing offshore equipment and gaining access to the pipeline. Considering the differences in damage consequences for offshore and onshore pipelines and production platforms, less frequent seismic hazards (larger earthquake hazards) should be considered for offshore pipelines than for onshore pipelines. This can be achieved by selecting annual probabilities of earthquake hazards for offshore pipelines that are less than what would be selected for onshore pipelines (i.e., longer average return periods for seismic events).

If life safety is the primary criteria, the annual probability for experiencing a design earthquake hazard for an offshore pipeline may not need to be as low as for an offshore production platform, because pipeline damage does not generally lead to direct life-safety consequences. Pipeline failures tend to be localized (at one or more locations) and repairs might be implemented in a relatively short time frame if the water depth is not great. Such disruptions would have limited adverse consequences with respect to life safety. A very important exception is offshore oil pipelines and pipelines located in very deep water for which the environmental consequences and costs associated with pipeline repairs may be very severe. In these cases, the design criteria may be more stringent that what is necessary to meet established life-safety performance objectives.

A.3 Perspective on Seismic Risk

The principal consequence of the rupture of a natural gas transmission pipeline is the potential for release and subsequent ignition of gas in areas where there is a potential for injury or significant property damage. Other consequences include service interruption and the cost of repair and cleanup. Rupture of liquid hydrocarbon pipelines may have severe environmental consequences that are of equal or greater concern to the pipeline owner and govern the conservatism in defining the earthquake hazard. One of the most important and difficult issues associated with earthquake risk mitigation for natural gas and liquid hydrocarbon pipelines is the determination of the appropriate level of investment in seismic hazard mitigation versus the benefit that would be derived. Costs and benefits are difficult to assess due to the limited knowledge of earthquake recurrence, the uncertainty involved in projecting pipeline damage, and the quantification of the impact of pipeline service interruptions.

Pipelines are subject to risk of damage due to a number of causes totally unrelated to earthquakes. Among these are corrosion, outside force, material failure, and construction defects. An analysis of reportable incidents for natural gas transmission and gathering lines in the U.S. (Jones et al., 1986) indicates that approximately 685 failures, classified as propagating ruptures, punctures, blowouts or tears, occurred over a 14.5-year period. The total length of natural gas transmission pipelines during this period was about 500,000 km. This leads to an average of approximately 1×10^{-4} failures per kilometer of pipeline per year. For a postulated 50-year service life, this failure rate equates to approximately 5×10^{-3} failures per kilometer or one failure per 200 km (Nyman and Hall, 1991).

If one considers the hypothetical case of an earthquake with an estimated recurrence interval of 500 years causing damage over a 100-km segment of the pipeline route, five such pipeline failures would be comparable to the statistics for normal operation. This failure rate probably represents an upper bound for most welded steel pipelines. Admittedly, this analogy is rough and approximate, but it does illustrate the order of magnitude of the relative threat posed by strong earthquakes compared to normal operation.

In light of the foregoing example, it seems appropriate that improvement of seismic resistance through capital expenditures should be tempered by recognition of the hazards associated with day-to-day operations. While mitigation of the seismic threat through design is usually the preferred alternative, it may be more reasonable in certain cases to focus attention on minimizing the consequences of destructive earthquakes. In particular, the safety impact of extensive pipeline damage can be reduced through improved line break isolation, earthquake contingency plans, repair plans, and seismic hardening of control systems and communications.

This Page Intentionally Left Blank

SEISMIC DESIGN PROVISIONS IN EXISTING STANDARDS

Requirements for liquid hydrocarbon pipelines in the United States are set forth in Title 49 of the Code of Federal Regulations (CFR), Parts 192 and 195 (U.S. Department of Transportation, 1998a, 1998b), which regulate the design, construction, operation, and maintenance of natural gas and crude oil pipelines, respectively. ASME B31.4 and ASME B31.8 are consensus standards developed in accordance with the requirements of the American National Standards Institute (ANSI) which have been developed and maintained by technical committees of the American Society of Mechanical Engineers (ASME) (1998, 2000). The ANSI standards are supplemented by industry standards such as API Recommended Practice 1111 for the design construction, operation, and maintenance of offshore hydrocarbon pipelines (American Petroleum Institute, 1993).

In Canada, liquid hydrocarbon and natural gas pipelines are designed in accordance with Canadian Standards Association (CSA) Z662, Design of Oil and Gas Pipeline Systems. CSA Z662 covers both onshore and offshore pipelines.

In Europe, two standards are commonly used to control the design and operation of offshore pipelines: British Standard BS 8010, Code of Practice for Pipelines, Part 3 (British Standards Institute, 1993), and Rules for Submarine Pipeline Systems published by Det Norske Veritas (DNV) (2000).

None of the aforementioned standards provide specific requirements for seismic design of crude oil and natural gas pipeline systems. Typically, these standards acknowledge that consideration should be given to the various types of seismic hazards, but they do not prescribe specific criteria or methodology. Reference is often made to "giving consideration to," "providing reasonable protection," or "taking reasonable precautions," but the level of design treatment is undefined. The responsibility for assuring that adequate provisions have been made to address seismic hazards is delegated to the pipeline designer and the appropriate regulatory body.

The references made by the above-listed standards to seismic design is summarized below.

B.1 ANSI B31.4, Pipeline Transportation Systems for Liquid Hydrocarbons and Other Liquids

ANSI B31.4 is the U.S. standard for the design, construction, operation, and maintenance of liquid hydrocarbons pipelines, both onshore and offshore. ANSI B31.4 makes only limited reference to seismic design by acknowledging the need to consider certain situations involving earthquake-induced loads. No specific criteria, requirements or guidelines are offered. The major objective is to create a general awareness of the need to evaluate seismic hazards.

1. Paragraph 401.5.3, *Earthquake* (relating to dynamic effects). "Consideration in the design shall be given to piping systems located in regions where earthquakes are

known to occur." This paragraph acknowledges the need for seismic design, but offers no guidance or specific requirements.

2. Paragraph 402.1, *General* (relating to design criteria). "… the design engineer shall provide reasonable protection to prevent damage to the pipeline from unusual external conditions which may be encountered in river crossings, offshore and inland coastal water areas, bridges, areas of heavy traffic, long self-supported spans, unstable ground, vibration, weight of special attachments, or forces resulting from abnormal thermal conditions." This provision goes on to state that protective measures, such as increasing the wall thickness, may be used. This provision simply acknowledges the possibility of extreme events for which some special protection is warranted. No specific requirements are set forth for any of these load conditions, nor is there any delineation of what constitutes "reasonable protection."

3. Paragraphs 402.3.3, *Limits of Calculated Stresses Due to Occasional Loads*, and 419.6.4, *Stress Values.* "The sum of the longitudinal stresses produced by pressure, live and dead loads, and those produced by occasional loads, such as wind or earthquake, shall not exceed 80% of the specified minimum yield strength of the pipe…" This limit is intended for aboveground piping or elevated pipeline spans and is not applicable to extreme situations involving large ground movements due to faulting or liquefaction.

B.2 ANSI B31.8, Gas Transmission and Distribution Piping Systems

ANSI B31.8 is the U.S. standard for the design, construction, and operation of onshore and offshore gas transmission and distribution systems. In a manner similar to the ANSI standard for liquids lines (B31.4), the ANSI B31.8 standard for gas transmission and distribution lines makes very limited reference to seismic design of onshore pipelines, but has more extensive treatment of seismic hazards (without specifics) for offshore pipelines (B31.8, Chapter 8).

The B31.8 provisions that mention seismic design are as follows:

1. Paragraph 833.4(c), relating to the calculation of longitudinal stress. External loads such as weight and wind that contribute to longitudinal bending stress for aboveground piping are mentioned. This section applies to primary seismic inertial loads but not to secondary loads on buried piping.

2. Paragraph 841.13, *Protection of Pipelines and Mains from Hazards*, Item (a). "When pipelines and mains must be installed where they will be subject to natural hazards, such as washouts, floods, unstable soil, landslides, earthquake related events (such as surface faulting, soil liquefaction, soil and slope instability characteristics), or other conditions which may cause serious movement of, or abnormal loads on, the pipeline, reasonable precautions shall be taken to protect the pipeline, such as increasing the wall thickness, constructing revetments, preventing erosion, and installing anchors." This paragraph effectively identifies the potential for seismic hazards but does not

prescribe any specific criteria or requirements for design or operational precautions or what constitutes "reasonable precautions."

3. Paragraph A835, *Anchorage for Buried Piping.* "When a submerged pipeline is to be laid across a known fault zone, or in an earthquake-prone area where new faults are a possibility, consideration shall be given to the need for flexibility in the pipeline system and its components to minimize the possibility of damage due to seismic activity."

4. Paragraph A841.1, *Design Conditions*, Item (f). Seismic activity is identified as a prospective offshore design condition.

5. Paragraph A841.33, *Design Environmental Conditions,* Item (d). Seismic events are identified as a prospective offshore environmental load condition.

6. Paragraph A842.23, *Alternate Design for Strain.* This paragraph permits design to strain criteria in excess of yield strain for situations where the pipeline experiences a predictable, noncyclic displacement of its support and provided the consequences of yielding are not detrimental to the integrity of the pipeline. The paragraph goes on to say that permissible strain criteria should be determined on the basis of available ductility and buckling behavior. This provision of B31.8 is quite important in that it offers confirmation of the appropriateness of using strain limits as the design criteria for pipelines subjected to seismic ground movements, albeit such limits are undefined.

7. Paragraph A843, *On-Bottom Stability.* "Pipeline design for lateral and vertical stability is governed by seafloor bathymetry, soil characteristics, and by hydrodynamic, seismic, and soil behavior events having a significant probability of occurrence during the life of the system. … The pipeline system shall be designed to prevent horizontal and vertical movements, or shall be designed so that any movements will be limited to values not causing design strength to be exceeded. …Typical factors to be considered in the stability design include: …(c) liquefaction, (d) slope failure." This paragraph states that offshore pipelines should be designed to withstand seismic effects without exceeding design strength, but there is no link back to the provision in Paragraph A842.23 for design on the basis of strain limits.

8. Paragraph A843.5, *Soil Liquefaction.* "Design for the effects of liquefaction shall be performed for areas of known or expected occurrence. …. Seismic design conditions used to predict the occurrence of bottom liquefaction or slope failure shall have the same recurrence interval as used for the operating design strength calculations for the pipeline." This paragraph calls for the design of offshore pipelines to mitigate the effects of liquefaction and slope failure, but no specific criteria or methodology are defined.

B.3 API Recommended Practice 1111, Design, Construction, Operation, and Maintenance of Offshore Hydrocarbon Pipelines

API Recommended Practice (RP) 1111 sets out criteria for the design of offshore pipelines. It is intended to be used in conjunction with ANSI B31.4 and B31.8 standards for liquids and gas transmission pipelines. The procedures presented in API RP 1111 are essentially the same as that prescribed by the ANSI standards, and the allowable stress provisions from B31.4 and B31.8 are incorporated by reference. The mention of seismic requirements are quite limited as summarized below:

1. Section 2.1.4, *Dynamic Forces*. A general statement is made that the design should consider dynamic forces imposed on the pipeline and the resulting stresses, and that these stresses may be caused by a number of possible loading conditions, one of which is seismic activity. The provision serves only as an alert to consider seismic events as a source of dynamic loads.

2. Section 2.4.2.1, *On-Bottom Stability.* The discussion of considerations for on-bottom stability includes the effects of natural phenomena. The potential for earthquakes to cause the liquefaction of sea-bottom sediments and associated settlement or floatation of a pipeline is specifically mentioned as a potential situation requiring consideration.

B.4 BS 8010, Code of Practice for Pipelines, Part 3, Pipelines Subsea: Design, Construction and Installation

British Standard BS 8010, Part 3, provides recommendations for the design, construction, installation, testing, and commissioning of subsea pipelines. BS 8010 contains numerous references to seismic activity as an environmental load condition that must be considered. The provisions of BS 8010 that relate to seismic design are listed below:

1. Section 4.2.2.5, *Functional and Environmental Loads.* Earthquakes are identified as an environmental load condition requiring consideration, and cross-reference is made to Appendix B of BS 8010 for further discussion.

2. Section 4.2.5.4, *Equivalent Stress*. This section specifies that equivalent stress (computed in accordance with the von Mises' stress criterion) shall be less than 0.96 times the specified minimum yield stress for environmental load conditions.

3. Section 4.2.6, *Alternative Design for Strain.* This section states that the limit on equivalent stress set forth in Section 4.2.5.4 may be replaced by an allowable strain limit of 0.1%.

4. Section 4.5.4.2, *Soil Instability*, Item (a). This section states that consideration should be given to stabilization enhancement methods in locations where the ground along the pipeline route might become unstable due to a number of reasons, including seismic activity.

5. Section 4.12.1, *Possible Causes of Damage*, Item (I). Seismic activity is named as a possible cause of damage that requires consideration.

6. Section B.1.10, *Seismic Action.* This section calls for consideration of the effects of seismic ground motions along the pipeline route. Specific mention is given to the possibility of soil liquefaction. No guidance is offered on the appropriate level of treatment.

7. Section B.2.7.5, *Liquefaction*, Item (b). This section calls for consideration of soil liquefaction, and seismic action is identified as a potential cause of liquefaction.

8. Section C.1.3, *Axial Compression*, and Section C.1.4, *Bending*. These two subsections under Appendix C, Buckling, provide stress limits for local buckling.

B.5 CSA Z662-96, Oil and Gas Pipeline Systems

The Canadian standard for oil and gas pipeline systems provides stress design requirements for operating pressure, thermal expansion ranges, temperature differential, and sustained force and wind loadings. Other load conditions are not specifically addressed. The Canadian standard provides for the design of pipelines using limit state criteria defined in its non-mandatory Appendix C, although the prescribed load conditions for which the limit state criteria are to be applied are the same as in the mandatory sections of the standard.

B.6 DNV Rules for Submarine Pipeline Systems

The DNV Rules for submarine pipeline systems specify requirements for the design, construction, installation, operation, and maintenance of subsea pipelines. The DNV Rules contain several references to seismic activity as a load condition that must be considered. These provisions are summarized below.

1. Section 2.1.1, *Environmental Phenomena*. This section requires consideration of all environmental phenomena that impair pipeline system function or reduce system reliability. Seismic activity is listed as an environmental phenomenon that should be considered.

2. Section 3.3.1.3, relating to environmental loads. This section states that the return period to be taken for environmental loads shall be greater than 100 years.

3. Section B.1, *Local Buckling*. This section of Appendix B provides methodology for determining critical buckling stress based upon a Ramberg-Osgood representation of the stress-strain curve for steel.

This Page Intentionally Left Blank

PROBABILISTIC SEISMIC HAZARD

Nearly all modern earthquake design codes rely on probabilistic seismic hazard analyses to define the level of ground shaking. The basic procedures for estimating the ground shaking hazard in a probabilistic hazard analysis are similar to those used in a deterministic approach where a specific earthquake magnitude and location are specified. The main difference in a probabilistic approach is that multiple earthquakes are considered to contribute to the level of ground shaking likely to be experienced at a particular location.

The general process for performing a probabilistic seismic hazard analysis includes the following steps, illustrated graphically in Figure C.1:

1. Characterize the type and location of earthquake source zones.

2. Define the frequency of occurrence of earthquakes of varying magnitude within the source zones.

3. For a particular location, use attenuation relationships to compute the level of ground shaking from each earthquake from each source zone and weight the resulting ground shaking by the likelihood of earthquake occurrence.

Earthquake source zones are typically characterized as point, line, or area sources (Figure C.2). A point source represents an earthquake at a single location and is typically incorporated into line-source or area-source models. A line source, often used to represent earthquakes occurring along faults, can have an earthquake point source centered at any portion of the line source considered to rupture in an earthquake. An area source is often used to model regions with no known active faults and point sources are assumed to occur at random locations within the defined area.

The rate of occurrence of earthquakes is estimated from regional earthquake records, regional strain rate information, or specific fault investigations that provide estimates of average fault slip rates. A particular concern in establishing earthquake occurrence rates is to maintain consistency between regional deformation associated with the model and deformation related to regional strain measurements.

Two common methods used to estimate recurrence rate for earthquakes of varying magnitude include the use of the Gutenberg-Richter relationship and a characteristic model of earthquake recurrence. The Guttenberg-Richter relationship assumes a continuous distribution of earthquake magnitudes between zero and the maximum magnitude for the particular fault. The form of this relationship is as follows:

$$\log N(M) = a - bM \qquad \text{(C-1)}$$

where:

$N(M)$ = earthquake moment magnitude $[6.0 < M < 8.0]$

a, b = constants determined from regional earthquake catalogs

The a parameter in (C-1) corresponds to a magnitude between –0.05 and +0.05. In probabilistic ground motion hazard analyses, it is customary to truncate the relationship at an earthquake magnitude between 5.00 and 6.50. This truncation is necessary to avoid overestimating regional deformation produced by a large number of very small earthquakes. For areas with known active faults, the maximum earthquake magnitude given by the Gutenberg-Richter equation is generally limited to the magnitude computed based upon empirical relationships (e.g., Wells and Coppersmith, 1994) between magnitude and fault length or fault area assuming the entire fault ruptures.

The concept of a characteristic earthquake is generally accepted as an appropriate means to address hazards from individual faults. The characteristic earthquake approach is based upon the hypothesis that earthquakes generated by a particular fault tend to have similar magnitudes instead of the continuous magnitude distribution assumed by the Gutenberg-Richter model. The characteristic earthquake is typically related to an earthquake that ruptures an entire fault segment.

For area sources, earthquake occurrence rates are nearly always based upon a Gutenberg-Richter recurrence model with the maximum earthquake magnitude estimated using available information and considerable judgment.

In addition to weighting the ground motions at a site produced by each earthquake source, the uncertainty in selection of attenuation relationship can be incorporated into the probabilistic hazard. This may be accomplished by selecting multiple attenuation relationships, with a weighting factor based upon judgment or by accounting for the variability of a particular attenuation relationship directly.

Probabilistic hazard studies produced for areas where there are no well-defined active faults (i.e., modeled entirely with area sources) have a common characteristic: ground motion estimates increase with decreasing probability of occurrence and these motions are associated with smaller magnitude earthquakes occurring closer to the site of interest.

For estimating wave propagation strains or assessing landslide hazard, the ground shaking estimates from a probabilistic hazard analysis can be used directly. For the assessment of liquefaction or lateral spread displacement, it is necessary to define an earthquake magnitude and distance. While this information is generally available as a by-product of the probabilistic hazard analysis, it is often not reported. Deaggregation studies extract information from probabilistic hazard analyses on the contribution of individual point sources within line and area source models. There is little guidance on how to select an appropriate combination of magnitude and distance from a deaggregation study. Past project experience indicates that selecting a combination that captures 50% to 84% of the total seismic hazard may be appropriate. This is illustrated in the Commentary.

The results of probabilistic hazard studies are of no value for estimating fault displacement. However, if probabilistic hazard studies are available for areas with

known fault activity, there will be information on specific faults used in the hazard study (e.g., fault length, fault width, slip rate, dip angle, type of faulting).

It is recommended that assistance from individuals with special expertise in defining earthquake surface fault hazards be used to fault motions for assessing pipeline performance. However, a very approximate estimate of the likelihood of an earthquake of the maximum magnitude on a fault can be made based upon the reported fault slip rate and fault dimensions. The key assumption in this approach is that all geologic slip is associated with the estimate of the maximum earthquake that can occur on a fault. This assumption overestimates the occurrence rate since it does not account for slippage from smaller, more frequent earthquakes. Nonetheless, the approach can be used to compare relative risk from numerous faults and is often adequate for performing preliminary engineering assessments.

The slip rate can be used to estimate the rate of accumulation of seismic moment using the definition of seismic moment rate, M_r:

$$M_r = \mu \cdot RLD \cdot FW \cdot sr \qquad \text{(C-2)}$$

where:

a, b	=	constants determined from regional earthquake catalogs
M_r	=	moment rate
μ	=	shear modulus of earth's crust (typically taken as $3x10^{10}$ N/m^2)
RLD	=	fault rupture length at depth
FW	=	fault width
sr	=	fault slip rate

The moment released, M_e by an earthquake of magnitude M is computed as

$$M_e = 10^{1.5(M)+9} \qquad \text{(C-3)}$$

The earthquake magnitude, M, can be estimated using empirical relationships from Wells and Coppersmith (1994), one of which is provided below:

$$M = 4.38 + 1.49 \cdot \log(RLD) \qquad (\sigma = 0.26 \text{ units of magnitude}) \qquad \text{(C-4)}$$

The mean recurrence period, RP, for an earthquake of magnitude M can be estimated as M_e/M_r which is given by the expression below.

$$RP = \frac{10^{1.5(M)+9}}{\mu \cdot RLD \cdot FW \cdot sr} \qquad \text{(C-5)}$$

By assuming that an earthquake of a selected magnitude is responsible for all of the fault slip, the simplified approach always overestimates the probability of occurrence of a

particular earthquake. Comparisons with published recurrence intervals for many faults in the United States indicate that the simplified approach typically overestimates earthquake probability by less than a factor of two. Since the simple approach always overestimates the likelihood of an earthquake of a specific magnitude, it will generally significantly underestimate the earthquake magnitude for a defined return period. This is the reason the simplified approach is limited to consideration of the maximum earthquake magnitude for a particular fault.

If the maximum magnitude earthquake on a particular fault is not judged to be appropriate or a more refined estimate of return period is needed, assistance from individuals with expertise in seismology is required.

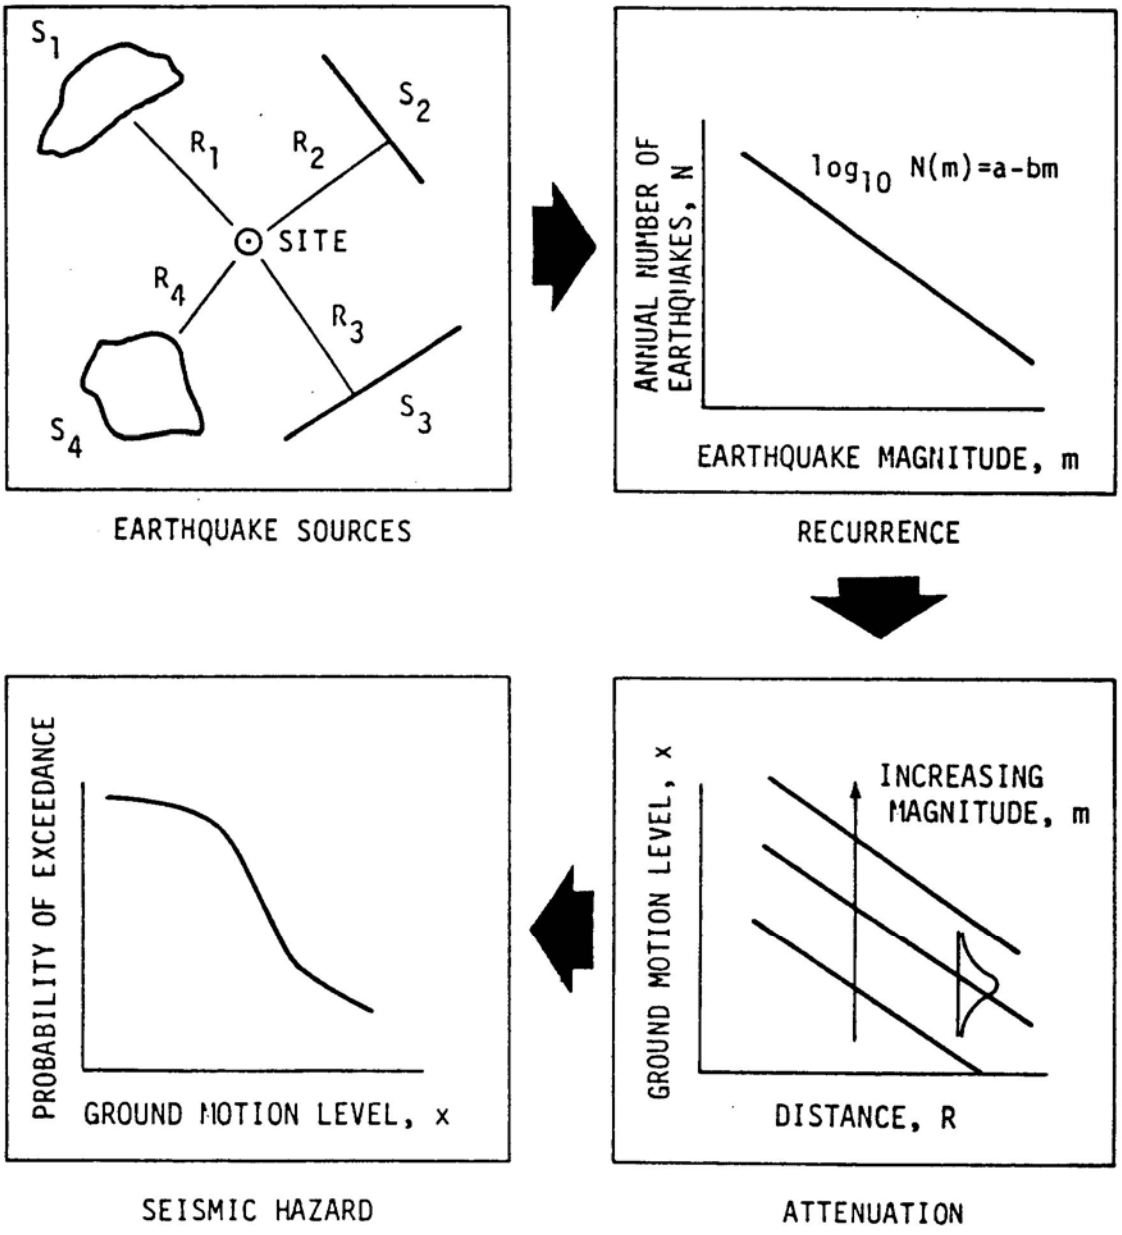

Figure C.1 Probabilistic Seismic Hazard Process (from ASCE, 1984)

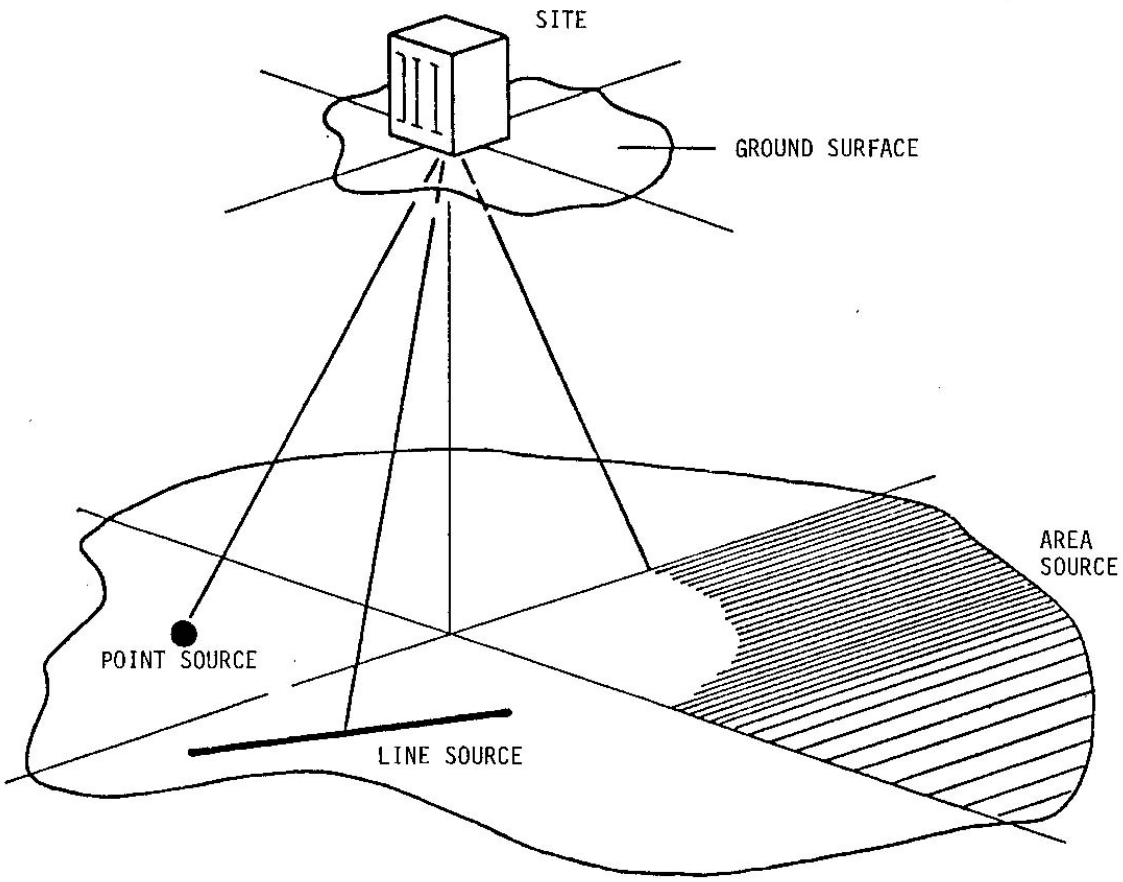

Figure C.2 Common Types of Earthquake Source Models (from ASCE, 1984)

EXAMPLE CALCULATIONS

This example calculation is provided to serve several purposes. First, the example illustrates the application of various equations provided in the guidelines. Second, the example provides a basis for understanding the magnitude of numerical values (e.g., ground displacements, soil spring forces) associated with estimating parameters for a seismic assessment of a buried pipeline. Finally, the example illustrates the processes involved in performing a seismic assessment of a buried pipeline. To assist in presenting the calculations, the example has been framed in the context of a hypothetical pipeline alignment. While parts of the example are extracted from actual past project experience, the results are for illustrative purposes only.

Problem Description:

The site in question is the portion of an NPS 20 pipeline alignment at the south bank of the Flowing River in the western United States. The NPS 20 pipeline crosses the river in a straight alignment. The site is being evaluated for potential liquefaction hazards. The plan and profile of the south side of the river crossing is shown in Figure D.1. The ground is typically flat south of the crossing (less than 0.5% slope) until the pipeline reaches a hill approximately 650 ft (200 m) south of the riverbank. Surface geology maps indicate the hill is an outcropping of weathered shale. The pipeline in the vicinity of the river crossing is classified as a Class 2 location in accordance with ASME B31.8.

The performance requirement established for the NPS 20 pipeline is defined as a mean annual probability of pipeline rupture from earthquake causes less than 0.2%. This is equivalent to a 500-year average return period. A review of available geologic maps and regional hazard information available from the government indicate two potential earthquake sources. One source is the Shakem fault, located 19.3 miles (31 km) from the river crossing. The other source is the Enditall fault, located more than 30 miles (48 km) from the site. Both faults are characterized by strike-slip fault movement with surface fault expression. Seismic parameters available for the two faults in question are summarized in Table 1. The variability in fault length and slip rate is for illustration purposes only. In actual practice, there is considerable variability in all fault descriptive parameters that are usually related to the particular interpretation of subsurface data by different geologists and seismologists.

Table 1: Summary of Fault Descriptive Parameters

Fault	Length, km (range)	Depth km	Slip mm/yr	Sediment Depth km
Shakem	80 (70 - 120)	11	5±2	1
Enditall	175 (100 - 250)	13	1±0.5	1

The pipeline, installed in 1960, is fabricated from API 5L Grade X42 seamless pipe with a coal tar coating. The pipe wall thickness is typically 0.280 inches (7.1 mm) except at the river crossing where the thickness is 0.375 inches (9.5 mm). The river crossing portion of the pipeline also has 3 inches (76 mm) of concrete coating for buoyancy control. The maximum allowable operating pressure for the pipeline is 825 psi (5,700 kPa) although the typical operating pressure is below 500 psi. No internal inspection of the pipeline has been performed to confirm the condition.

Liquefaction is considered possible based upon regional seismic hazard maps and knowledge of past subsurface investigations for other construction projects near the pipeline crossing. Given this information, subsurface investigations to collect SPT (one location) and CPT data (three locations) were performed at the sites indicated in Figure D.1. SPT and CPT data were collected at a common location to provide a direct correlation between the SPT and CPT data. In addition to the SPT data, SPT drilling provided an opportunity to collect soil samples. Samples were collected from each SPT using sample liners and later evaluated to determine density and grain size distribution. Some results from the subsurface investigation are provided in Table 2 and Figures D.2 through D.4.

Table 2: Selected Data from Subsurface Investigations

SPT 1		**CPT 3**	
Sample Depth	20 ft	Test Depth	20 ft
SPT Value	8	q_c (bars)	50
% Fines	19	f_s (bars)	0.2
Average Density (pcf)	110		

Step 1: Define Earthquake for Performing the Seismic Assessment

In most cases, the earthquake hazard will be defined by geologists or seismologists familiar with the tectonic setting of the site being assessed. The following approach, based upon methods described in Section 2 and Appendix C is provided to illustrate the process for obtaining an approximate quantification of the seismic hazard with limited data.

The information on fault length, depth, slip rate, and direction of slip are used to estimate the risk of an earthquake and the ground shaking levels in the event of an earthquake. The calculations necessary to perform this estimate for the Shakem fault are summarized below.

Earthquake Magnitude:

Use the Wells and Coppersmith (1994) relationship for unknown or unspecified type of faulting

$$M = 4.38 + 1.49\left[\log(RLD)\right] = 4.38 + 1.49\left[\log(80)\right] = 7.2$$

Mean Recurrence Interval:

$\mu = 3(10)^{10}$ N/m^2

$M_e = 10^{1.5(M)+9} = 10^{1.5(7.2)+9} = 6.31(10)^{19}$ N-m

$M_r = \mu \cdot RLD \cdot FW \cdot sr = 3(10)^{10}(80,000)(11,000)(.005) = 1.32(10)^{17}$ N-m/yr

Mean recurrence interval estimated to be no more frequent than $\frac{M_e}{M_r} = 478$ years or approximately 500 years.

Amount of Fault Movement:

Although the pipeline does not cross a fault, the design fault dispalcements are computed for the purpose of the example problem. The pipeline is in a Class 2 location so the design fault displacement will be based upon the mean average fault displacement. For the Shakem fault:

$\log(AD) = 0.88SRL - 1.43 = 0.88\log(80) - 1.43 = 0.24$

AD = 1.8 m

The potential variability in the above estimates of fault movement and return period can be estimated by examining the results for possible combinations of fault rupture length and slip rate. The results are summarized in the following tables.

Table 3a: Earthquake Magnitude from Fault Rupture Length

Fault Rupture Length, km		
70	**80**	**120**
7.1	7.2	7.5

Table 3b: Mean Fault Displacement from Fault Rupture Length

Fault Rupture Length, km		
70	**80**	**120**
1.6 m	1.8 m	2.5 m

Table 3c: Earthquake Recurrence Interval (years)

Slip Rate	Fault Rupture Length, km		
mm/yr	**70**	**80**	**120**
3	710	840	1,390
5	430	500	830
7	306	360	600

Similar values for the Enditall fault are provided below:

Magnitude: 7.4 - 8.0

Fault Movement: 2.1 - 4.8 m

Recurrence Interval: 1,120 - 14,430 years

For the best estimate fault parameters, the Enditall fault average return period is estimated to be 5,610 years compared to the approximately 500 years for the Shakem fault. If fault crossing evaluations were to be performed for the Enditall fault, the design fault displacements would be obtained by multiplying the mean average fault displacement by 0.18, the performance goal (500 years) divided by half of the average return period of the fault (2,805 years). This would result in design fault displacements of 0.38 m to 0.86 m. Since both faults are strike-slip, there is no need for a correction to derive fault displacement components in three orthogonal displacements.

It is important to note the considerable variability in the estimates of the earthquake hazard. The level of uncertainty indicated by the results in Table 3 is typical of actual experience in estimating the earthquake hazard. It is possible, but not certain, that additional geologic investigations including trenching across the fault, deep borings, or seismic refraction studies could better define the basic fault descriptors.

PGA at Site:

Use Campbell attenuation relationship for a soil site:

$F = 0 \qquad S_{SR} = 0 \qquad S_{HR} = 0 \qquad R = 31$

$H_T = 0 \qquad H_S = 1 \qquad H_B = 12 \qquad \alpha = 90^\circ$

$$W = 10^{-1.01+0.32M} = 10^{-1.01+0.32(7.2)} = 16$$

$$d_S = \frac{1}{2}\left[H_B + H_T - W\sin(\alpha)\right] \geq H_S = \frac{1}{2}\left[12 + 0 - 16\right] = -3.85$$

$d_S = H_S = 1$

$R_s = \sqrt{d_S^2 + R^2} = \sqrt{1^2 + 33^2} = 31 \text{ km}$

$$\ln(PGA) = -3.512 + 0.904M - 1.328\ln\sqrt{R_S^2 + \left[0.149e^{0.647M}\right]^2} + \left[1.125 - 0.112\ln(R_S) - 0.0957M\right]F + \left[0.440 - 0.171\ln(R_S)\right]S_{SR} + \left[0.405 - 0.222\ln(R_S)\right]S_{HR} + f_A(D) + E\Phi^{-1}(x)$$

$$= -3.512 + 0.904(7.2) - 1.328\ln\sqrt{31^2 + \left[0.149e^{0.647(7.2)}\right]^2}$$

PGA = 0.18 *g*

The range of *PGA*, adopting the variability in earthquake magnitude from Table 3 and not including variability in the Campbell attenuation relationship, is 0.17 - 0.22 *g*. Similar *PGA* values for the Enditall fault are 0.13 *g* to 0.20 *g*.

Although the levels of ground shaking are comparable for the Shakem and Enditall faults, the Shakem fault is determined to be the controlling earthquake hazard because the recurrence interval is more compatible with the stated performance goal.

For the remainder of this example, the central fault description values (length = 80 km, slip rate = 5 mm/yr) are used.

Step 2: Assess Liquefaction Potential for Subsurface Soils

Calculations to assess the potential for liquefaction are performed for the same depth at location 1 where SPT and CPT data were collected. For the SPT calculations, hammer energy was assumed to be 60% and the tests were performed with a standard diameter sampler. A gradation curve for a sample retrieved at the depth being assessed for location 1 is provided in Figure D.4.

Depth = 20 ft = 6.1 m

Depth to water table = 6 ft (1.8 m) at time of test

Dry density = 110 pcf

Total overburden stress = $\sigma_{vo} = 20(110) = 2{,}200$ psf = 1.1 tsf = 105 kPa

Effective stress = $\sigma'_{vo} = \sigma_{vo} - 62.4(20 - 6) = 1{,}326$ psf =0.663 tsf = 63.5 kPa

$P_a = 14.5$ psi = 100 kPa = 2,088 psf

z = D/m = 6.1

$$r_d = \frac{1 - 0.4113\sqrt{z} + 0.04052z + 0.001753z^{1.5}}{1 - 0.4177\sqrt{z} + 0.05729z - 0.006205z^{1.5} + 0.001210z^2}$$

$$r_d = \frac{1 - 0.4113\sqrt{6.1} + 0.04052(6.1) + 0.001753(6.1)^{1.5}}{1 - 0.4177\sqrt{6.1} + 0.05729(6.1) - 0.006205(6.1)^{1.5} + 0.001210(6.1)^2} = 0.96$$

$$CSR = 0.65PGA\left(\frac{\sigma_{vo}}{\sigma'_{vo}}\right) r_d = 0.65(0.18)\left(\frac{2,200}{1,326}\right)0.96 = 0.19$$

SPT Assessment:

$N = 8$

$$C_N = \sqrt{\frac{P_a}{\sigma'_{vo}}} = \sqrt{\frac{2,088}{2,200}} = 1.25$$

$$C_R = 0.75 + 0.25\frac{(z-4)}{6} = 0.75 + 0.25\frac{(6.1-4)}{6} = 0.84$$

$FC = 19\%$

$$\alpha = e^{1.76 - \frac{190}{FC^2}} = e^{1.76 - \frac{190}{19^2}} = 3.23$$

$$\beta = 0.99 + \frac{FC^{1.5}}{1000} = 0.99 + \frac{19^{1.5}}{1000} = 1.07$$

$$(N_1)_{60} = N \cdot C_N \cdot C_E \cdot C_B \cdot C_R \cdot C_S = 8 \cdot 1.26 \cdot 1 \cdot 1 \cdot 0.84 \cdot 1 = 8.4$$

$$(N_1)_{60FC} = \alpha + \beta(N_1)_{60} = 3.23 + 1.07(8.4) = 12.2$$

$$MSF = \frac{10^{3.81}}{M^{4.42}} = \frac{10^{3.81}}{7.2^{4.42}} = 1.05$$

K_σ is 1.0 since the effective stress is less than the reference pressure, P_a

$$CRR = \left(\frac{4.8(10)^{-2} - 4.721(10)^{-3}x + 6.136(10)^{-4}x^2 - 1.673(10)^{-5}x^3}{1 - 1.248(10)^{-1}x + 9.578(10)^{-3}x^2 - 3.285(10)^{-4}x^3 + 3.714(10)^{-6}x^4}\right) MSF \cdot K_\sigma$$

$$= \left(\frac{4.8(10)^{-2} - 4.721(10)^{-3}12.2 + 6.136(10)^{-4}12.2^2 - 1.673(10)^{-5}12.2^3}{1 - 1.248(10)^{-1}12.2 + 9.578(10)^{-3}12.2^2 - 3.285(10)^{-4}12.2^3 + 3.714(10)^{-6}12.2^4}\right) 1.05 \cdot 1.0$$

$$= 0.14$$

Since the CRR of 0.14 is less than the CSR of 0.19, liquefaction is expected for 0.18 *g* *PGA*.

CPT Assessment:

q_c = 50 bar = 5,000 kPa

f_s = 0.2 bar = 20 kPa

$$F = \left[\frac{f_s}{q_c - P_a}\right]100\% = \left[\frac{20}{5000-100}\right]100\% = 0.41\%$$

$$Q_1 = \frac{q_c - \sigma_{vo}}{P_a}\left(\frac{P_a}{\sigma'_{vo}}\right) = \frac{5000-105}{100}\left(\frac{100}{63.5}\right) = 77.1$$

$$I_1 = \sqrt{\left(3.47 - \log Q_1\right)^2 + \left(1.22 + \log F\right)^2} = \sqrt{\left(3.47 - \log 77.1\right)^2 + \left(1.22 + \log 0.41\right)^2} = 1.79$$

$$Q_{0.5} = \frac{q_c - \sigma_{vo}}{100\text{ kPa}}\left(\frac{100\text{ kPa}}{\sigma'_{vo}}\right)^{0.5} = \frac{5000-105}{100}\left(\frac{100}{63.5}\right)^{0.5} = 61.4$$

$$I_{0.5} = \sqrt{\left(3.47 - \log Q_{0.5}\right)^2 + \left(1.22 + \log F\right)^2} = \sqrt{\left(3.47 - \log 61.4\right)^2 + \left(1.22 + \log 0.41\right)^2} = 1.88$$

n = 0.5

$$C_Q = \left(\frac{P_a}{\sigma'_{vo}}\right)^n = \left(\frac{100}{63.5}\right)^{0.5} = 1.26$$

$$\begin{aligned} K_c &= -17.88 + 33.75I_n - 21.63I_n^2 + 5.581I_n^3 - 0.403I_n^4 \\ &= -17.88 + 33.75(1.88) - 21.63(1.88)^2 + 5.581(1.88)^3 - 0.403(1.88)^4 \\ &= 1.16 \end{aligned}$$

$$\left(q_{c1N}\right)_{FC} = K_c \cdot C_Q\left(\frac{q_c}{P_a}\right) = 1.26 \cdot 1.16\left(\frac{5,000}{100}\right) = 73$$

$$CRR = \left[93\left(\frac{(q_{c1N})_{FC}}{1000}\right)^3 + 0.08\right]MSF = \left[93\left(\frac{73}{1000}\right)^3 + 0.08\right]1.05 = 0.12$$

Since the CRR of 0.12 is less than the CSR of 0.19, liquefaction is expected for 0.18 *g* *PGA*.

From similar calculations for the other boring locations, the extent of liquefiable material for the site is estimated. The cross-section of the site is provided in Figure D.1 that indicates the extent of potentially liquefiable material at the riverbank.

Step 3: Assess Potential for Lateral Spread Movement

The site is representative of a free face condition. For this example, thickness of saturated sand deposits with $(N_1)_{60}$ less than 15 is taken as 75% of the average liquefiable thickness of 15.3 m or 11.5 m, the average fines content of the material with $(N_1)_{60}$ less than 15 is 5%, and $D50_{15}$ is 0.10 mm. In practice, this determination is made based upon a review of all SPT and CPT data.

Lateral spread displacement for the onshore portion of the crossing can be estimated as a function of the distance from the crest of the bank using a free-face condition.

$M = 7.2$

$R = 31$ km

$R_o = 10^{0.89M-5.64} = 10^{0.89(7.2)-5.64} = 5.86$

$R^* = R + R_o = 36.86$

$T_{15} = 11.5$

$F_{15} = 5$

$D50_{15} = 0.10$

$H = 20$

For sloping ground conditions:

$$\begin{aligned} Log(LSD) = & -16.213 + 1.532M - 1.406LogR^* \\ & - 0.012R + 0.338LogS + 0.540LogT_{15} \\ & + 3.413Log(100 - F_{15}) - 0.795Log(D50_{15} + 0.1) \end{aligned}$$

For free-face conditions:

$$\begin{aligned} Log(LSD) = & -16.713 + 1.532M - 1.406LogR^* \\ & - 0.012R + 0.592LogW + 0.540LogT_{15} \\ & + 3.413Log(100 - F_{15}) - 0.795Log(D50_{15} + 0.1) \end{aligned}$$

Lateral spread displacement is computed for various distances from the toe of the riverbank as summarized in Table 4. The maximum distance of interest coincides with a transition between river deposits and the weathered shale hillsides bounding the river. Lateral spread displacements on the slope of the bank are estimated using the ground

slope equation even though the slope exceeds the 0% to 6% recommended range in slope for applicability of the equation. This is likely a conservative assumption considering the much larger displacements estimated by the ground slope equation compared to the free-face equation. The surface ground displacement profile assumes free-face conditions beyond the crest of the riverbank since the ground profile in this area is relatively flat. This assumption is consistent with the formulation of data used in the Youd, Hansen, and Bartlett equations. The resulting surface ground displacement profile is illustrated in Figure D.5.

Table 4: Computed Lateral Spread Displacements

Station (m)	Distance from Toe (m)	W & S (%)	Slope LSD (m)	Free-Face LSD (m)
2355	0	N/A	N/A	N/A
2596	241	8.3	2.7	N/A
2605	250	7.8	2.6	1.4
2655	300	6.7	2.5	1.3
2705	350	5.7	2.4	1.2
2739	384	5.2	2.3	1.1

Step 4: Estimate Relative Lateral Spread Displacement Affecting the Pipeline

Typically, the ground displacement resulting in loads on the pipeline is less than that indicated in the plot of surface displacements for portions of the pipeline within the liquefiable material. The ground displacements at the pipeline depth are estimated as a function of the ratio of the liquefiable layer depth below the pipe to the total depth of the liquefiable layer. Alternatively, a more conservative approach is to assume that the pipe is subjected to the same horizontal ground displacements as the surface. This assumption is consistent with block-like movement of the liquefiable layer over the deeper non-liquefiable soil.

Step 5: Compute Vertical Settlement from Pore Water Dissipation

The amount of vertical settlement related to pore water dissipation is estimated using the average computed factor of safety against liquefaction and Figure 2.4. For the location previously assessed, the factor of safety against liquefaction is *CRR/CSR* = 0.13/0.19 = 0.7. Figure 2.4 was developed for clean sands. The use of $(N_1)_{60FC}$ = 12.2 instead of $(N_1)_{60}$ is assumed to account for the presence of fine-grained material. From Figure 2.4, the post-liquefaction volumetric strain at the location where liquefaction is estimated as approximately 3%. The vertical settlement that the pipeline will experience is estimated as 3% of the depth of liquefiable soil beneath the pipeline and is plotted in Figure D.5. The maximum differential vertical displacements that the pipeline is exposed to is less than 15 cm over 35 m of pipe. This is sufficiently small to be neglected in the assessment of pipeline performance.

Step 6: Compute the Soil Spring Properties Along the Pipeline

Soil spring properties vary with soil material and pipeline burial depth. Within the same soil material, soil spring values are assumed to vary linearly between two different burial depths. The following example computes soil springs near stations 2453 and 2749.

Station 2453:

This location is within the zone of soil expected to liquefy. The soil strength is treated as if the soil were a cohesive material ($\phi = 0$) with an undrained shear strength equal to 20% of the effective overburden stress.

Soil cover = 8.4 m = 27.6 ft

Water table elevation = -2.75 m = -9 ft

Ground surface elevation = -13.8 m = -45.3 ft

Diameter = D+2(3inches) = 26 inches = 2.167 feet = 0.660 m

Material = liquefied soil

$H = C + D/2$ = 8.73 m = 28.6 ft

H/D = 13.2

Effective stress = 28.6(110-62.4) = 1,361 psf = 65 kPa

c = 0.2(1,361) = 272 psf = 0.272 ksf = 13 kPa

The primary direction of soil movement is in the axial direction. Therefore, assume all lateral (horizontal and vertical) movement is confined to the soils immediately surrounding the pipeline.

Axial Soil Spring:

$$\alpha = 0.608 - 0.123c - \frac{0.274}{c^2+1} + \frac{0.695}{c^3+1}$$

$$= 0.608 - 0.123(0.272) - \frac{0.274}{(0.272)^2+1} + \frac{0.695}{(0.272)^3+1} = 1.0$$

$$T_u = \pi D \alpha c + \pi D H \bar{\gamma}\left(\frac{1+K_o}{2}\right)\tan(\delta) = \pi(2.167)(1.0)(272) = 1{,}851\frac{\text{lb}}{\text{ft}} = 27\frac{\text{kN}}{\text{m}}$$

Horizontal Soil Spring:

$$N_{ch} = 6.752 + 0.065\left(\frac{H}{D}\right) - \frac{11.063}{\left(\frac{H}{D}+1\right)^2} + \frac{7.119}{\left(\frac{H}{D}+1\right)^3}$$

$$= 6.752 + 0.065(13.2) - \frac{11.063}{(13.2+1)^2} + \frac{7.119}{(13.2+1)^3}$$

$$= 7.6$$

$$P_u = N_{ch}cD + N_{qh}\bar{\gamma}HD = 7.6(272)(2.167) = 4{,}480\frac{\text{lb}}{\text{ft}} = 65.4\frac{\text{kN}}{\text{m}}$$

$$\Delta_p = 0.04\left(H + \frac{D}{2}\right) = 0.04\left(12 \cdot 28.6 + \frac{22.167}{2}\right) = 14 \text{ inches } = 36 \text{ cm}$$

Vertical Bearing Soil Spring:

$$N_c = \cot(\phi + 0.001)\left[e^{\pi \tan(\phi+0.001)} \tan^2\left(45 + \frac{\phi + 0.001}{2}\right) - 1\right]$$

$$= \cot(0.001)\left[e^{\pi \tan(0.001)} \tan^2\left(45 + \frac{0.001}{2}\right) - 1\right] = 5.14$$

$$N_q = e^{\pi \tan(\phi+0.001)} \tan^2\left(45 + \frac{\phi + 0.001}{2}\right) = e^{\pi \tan(0.001)} \tan^2\left(45 + \frac{0.001}{2}\right) = 1$$

$$N_\gamma = e^{0.18\varphi - 2.5} = e^{-2.5} \approx 0$$

$$Q_d = N_c cD + N_q \bar{\gamma} HD + N_\gamma \gamma \frac{D^2}{2}$$

$$= 5.14(272)(2.167) + (110 - 62.4)(2.167)(28.7) = 5{,}990\frac{\text{lb}}{\text{ft}} = 87.4\frac{\text{kN}}{\text{m}}$$

$$\Delta_{qd} = 0.125D = 0.125(26) = 3.3 \text{ inches } = 84 \text{ cm}$$

Vertical Uplift Soil Spring:

$$N_{cv} = 2\left(\frac{H}{D}\right) \le 8$$

$$= 2(9.5) = 19 > 8$$

$$N_{cv} = 8$$

$$Q_u = N_{cv}S_u D + N_{qv}\bar{\gamma}HD = 8(272)(2.167) = 4{,}715\frac{\text{lb}}{\text{ft}} = 68.8\frac{\text{kN}}{\text{m}}$$

$$\Delta_{qu} = \frac{0.12H(N_{qv}\bar{\gamma}HD) + 0.1H(N_{cv}cD)}{N_{cv}cD + N_{qv}\bar{\gamma}HD} = 0.1H = 0.1(28.7\text{ft})\left(12\frac{\text{in}}{\text{ft}}\right) = 34 \text{ inches} = 86 \text{ cm}$$

Station 2749:

Soil Cover = 4.9 ft (1.50 m)

Diameter = D = 20 inches = 1.667 ft = 0.508 m

Material = granular (c = 0)

$H = C + D/2 = 4.9(12)+.5(20) = 68.8$ inches = 5.733 ft = 1.75 m

$H/D = 68.8/20 = 3.4$

The internal friction angle is taken to be 35°.

The pipe is coated with fusion bonded epoxy. Use $\delta = 0.6\phi = 0.6(35) = 21°$

The primary direction of soil movement is in the axial direction. Therefore, assume all lateral (horizontal and vertical) movement is confined to the soils immediately surrounding the pipeline.

Axial Soil Spring:

$$T_u = \pi D\alpha c + \pi DH\bar{\gamma}\left(\frac{1+K_o}{2}\right)\tan(\delta)$$

$$= \pi(1.667)(5.733)(110)\left(\frac{1+0.5}{2}\right)\tan(21^\circ) = 950\frac{\text{lb}}{\text{ft}} = 13.9\frac{\text{kN}}{\text{m}}$$

Horizontal Soil Spring:

$$N_{qh} = 6.816 + 2.019\frac{H}{D} - 0.146\left(\frac{H}{D}\right)^2 + 0.00765\left(\frac{H}{D}\right)^3 - 1.683(10)^{-4}\left(\frac{H}{D}\right)^4$$

$$= 6.816 + 2.019(3.4) - 0.146(3.4)^2 + 0.007651(3.4)^3 - 1.683(10)^{-4}(3.4)^4$$

$$= 12.3$$

$$P_u = N_{ch}cD + N_{qh}\bar{\gamma}HD = 12.3(110)(5.733)(1.667) = 12{,}930\frac{\text{lb}}{\text{ft}} = 189\frac{\text{kN}}{\text{m}}$$

$$\Delta_p = 0.04\left(H + \frac{D}{2}\right) = 0.04\left(12\cdot 5.733 + \frac{20}{2}\right) = 3.2 \text{ inches} = 8 \text{ cm}$$

Vertical Bearing Soil Spring:

$$N_q = e^{\pi \tan(\phi)} \tan^2\left(45 + \frac{\phi}{2}\right) = e^{\pi \tan(35)} \tan^2\left(45 + \frac{35}{2}\right) = 33$$

$$N_c = \cot(\phi + 0.001)\left[e^{\pi \tan(\phi + 0.001)} \tan^2\left(45 + \frac{\phi + 0.001}{2}\right) - 1\right] = \cot(35)\left[N_q - 1\right] = 46$$

$$N_\gamma = e^{(0.18\phi - 2.5)}$$
$$= e^{(0.18(35) - 2.5)} = 45$$

$$Q_d = N_c c D + N_q \bar{\gamma} H D + N_\gamma \gamma \frac{D^2}{2}$$
$$= 33(110)(5.733)(1.667) + (45)(110)\frac{(1.667)^2}{2}$$
$$= 41{,}570 \frac{\text{lb}}{\text{ft}} = 607 \frac{\text{kN}}{\text{m}}$$

$$\Delta_{qd} = 0.125D = 0.125(20) = 2.5 \text{ inches} = 5 \text{ cm}$$

Vertical Uplift Soil Spring:

$$N_{qv} = \tan(\phi)\left(\frac{\phi}{44}\right)\left(\frac{H}{D}\right) = \tan(35)\left(\frac{35}{44}\right)3.4 = 1.9$$

$$Q_u = N_{cv} S_u D + N_{qv} \bar{\gamma} H D = 1.62(110)(4.833)(1.667) = 1{,}431 \approx 1{,}430 \frac{\text{lb}}{\text{ft}}$$

$$\Delta_{qu} = \frac{0.12H(N_{qv}\bar{\gamma}HD) + 0.1H(N_{cv}cD)}{N_{cv}cD + N_{qv}\bar{\gamma}HD} = 0.12H = 0.12(58) = 7.0 \text{ inches}$$

Step 7: Perform Analysis

The analytical model for assessing pipeline response is provided in Figure D.6. In plan, the pipeline is straight with the pipe anchored against movement at the center of the river crossing and at a point approximately 1,000 ft south of the ground deformation boundary. Anchoring the pipeline at the center of the river assumes that that north bank may experience a similar ground failure and the center of the river is a point of symmetry. If no instability of the north bank occurs, this assumption will lead to an overestimate of the pipe strains at the center of the river and an underestimate of the pipe strains at the onshore ground failure boundary. The southerly anchorage point was determined based upon the recommendation in Section 4.4.

$$L_{anchor} = \frac{\pi D t \sigma_y}{T_u} = \frac{\pi(26)(0.375)52,000}{2,100} = 758 \text{ ft} = 231 \text{ m}$$

The length of the pipe elements is one pipe diameter within 100 feet of the ground displacement boundaries. Between the zones with element length of 1 pipe diameter, the pipe elements are allowed to be up to 10 feet long.

No horizontal or vertical soil springs are specified more than 100 feet from the ground displacement boundaries as the pipeline is only exposed to axial loading. Lateral movement (horizontal and vertical) is prevented for this portion of the analytical model. The ground displacement pattern is applied in 120 equal increments to a maximum displacement that is about 50% greater (4 m) than the estimates from Step 4 (2.9 m). This allows the behavior of the pipeline to be evaluated for alternate assumptions that might increase the amount of applied ground displacement.

The amount of axial ground movement relative to the pipe is provided in Figure D.7a. As can be seen in Figure D.7a, the pipeline response is nearly separated between the head and toe regions of the lateral spread. The onshore portion of the pipeline acts to restrain the pipe from ground displacements creating tension in the pipe at the head of the lateral spread. Near the toe of the lateral spread, the ground displacement produces compression in the pipe that is resisted by the pipe outside of the zone of ground displacement. Figure D.7b illustrates the variation of maximum strain magnitude (tension or compression) along the pipeline at a maximum ground displacement of 4 m. The location of maximum tensile and compressive longitudinal strains are also indicated in Figure D.7b.

The variation in maximum longitudinal strain as a function of maximum ground displacement magnitude is shown in Figure D.8. For a specific ground displacement value, the strains plotted in Figure D.8 represent the largest total strain at any of 8 equidistant circumferential locations around the pipe cross-section at any location in the pipe model. For the ground displacement estimated in Step 4, the maximum strain is approximately 0.8% tension and 0.45% compression.

Step 8: Assess Nominal Pipeline Performance for Computed Strain Levels

An assessment will first be performed assuming the pipeline construction meets the requirements of Section 3.1. For a performance requirement that pressure integrity be maintained, the allowable longitudinal tensile strain limit is assumed to be 4%. The corresponding longitudinal compressive strain limit is computed as follows:

For the concrete-coated pipe:

$$\varepsilon_{cp} = 1.76\frac{t}{D} = 1.76\frac{.375}{20} = 3.3\%$$

For the onshore portion of the pipeline (t = 0.280 inches)

$$\varepsilon_{cp} = 1.76\frac{t}{D} = 1.76\frac{.28}{20} = 2.5\%$$

The pipe strain computed for 2.9 m of maximum ground displacement is far less than the above strain limits. On this basis, it is clear that the pipeline is not at risk for the ground displacements modeled in the analysis.

Additional analyses that should be performed, but are not included in this example problem, include the following modifications:

1. Variation in the soil springs to account for uncertainties in the estimated values.

2. Variation in the ground displacement pattern that might include assessing the pipeline assuming the surface ground displacements occur at the pipeline depth.

3. Extension of the pipeline model to represent a condition at the center of the river in which the pipeline is not anchored.

Step 9: Assess Potential for Landslide Hazard South of River Crossing

In addition to the lateral spread displacement, the slope south of the river is examined to determine if a more detailed geotechnical investigation of potential slope instability is necessary. The pipeline is located within the near-surface granular soils (Group B in Figure 2.8) that overly the weathered shale (Group C in Figure 2.8) of the hill. Two potential slide mechanisms are considered:

1. A shallow disruptive slide consisting of failure at the interface between surface soils and the underlying weathered shale.

2. A deep coherent slide within the weathered shale.

The weathered shale is assumed to provide a low-permeability boundary. Therefore, the interface between the surface soil and the weathered shale is assumed to be "wet" while the weathered shale is considered to be "dry." Noting that the slope of the hillside is 10%, the critical acceleration for sliding is estimated from Figure 2.8 to be 0.24 *g* for the disruptive slide and 0.20 *g* for the coherent slide.

The ground motions at the hillside are better represented by using soft rock conditions in the attenuation relationship (S_{sr} = 1). In the Campbell attenuation relationship, this results in the following additional factor:

$$0.44 - 0.17 \ln R = 0.44 - 0.17 \ln(40) = -0.187$$

The following correction factor is applied to the *PGA*:

$$PGA \cdot e^{-0.187} = 0.18\ g \cdot 0.83 = 0.15\ g$$

Since the *PGA* is less than the critical acceleration, there are no concerns for potential landslide movements.

Subject: Preliminary Hydrologic and Hydraulic Modeling for the Proposed Giovannoni Logistics Center

Introduction & Project Description

The Giovannoni project (Project) is located on a 208-acre site in the City of American Canyon. The site sits to the west of Highway 29, north of Green Island Road, and south of the developing Napa Logistics Park. The existing property consists of open space, with a total elevation variance of roughly 30 feet; two highpoints to the southeast and southwest of the Project area slope gradually north to a seasonal wetland that discharges into No Name Creek. Along with the Project area, the creek collects runoff from roughly 280 acres of vineyards, open space and previously developed industrial land uses, the majority of which lies to the east of Highway 29.

The first phase of the Project, referred to as the Giovannoni Logistics Center East and covered herein, proposes the construction of two warehouses (gross square footage of the two buildings is roughly one million square feet) along with parking lots to accommodate semi-trucks, trailers, and worker vehicles on roughly 70 acres. The runoff from the developed area will be managed by multiple stormwater facilities on the northern side of the Property designed to meet flood control requirements set forth by the City of American Canyon Department of Public Works and stormwater treatment and flow-duration control requirements outlined in the state-wide MS4 General Permit.

Although not yet constructed, the City of American Canyon plans to extend Devlin Road from its current terminus at the southern end of the Napa Logistics Park, south to intersect with Green Island Road (see **Figure 1)**. This planned extension will serve as the western boundary for the first phase of the Project. Stormwater runoff that, prior to the construction of the road, would flow from east to west through the northern portion of the site will now be directed through four 2-ft by 4-ft concrete box culverts located beneath the roadway. A hydrologic and hydraulic analysis for the new roadway, entitled Devlin Road and Vine Trail Extension, was completed in August 2020 by GHD and will be referred to herein as the "Devlin Road Analysis".

Purpose of the Study

This study seeks to model, assess, and outline how the changes in existing, and proposed land cover, along with the proposed construction of Devlin Road, will impact the hydrology and

hydraulics of the creek directly downstream of the Project area and along the reach to its confluence with the Napa River.

Standards & Methods

In compliance with American Canyon Department of Public Works Engineering Standards and Specifications for Public Improvements (1995) where stormwater detention is utilized, Contra Costa County Flood Control (Flood Control) methodology was used to create the hydrologic model of the pre- and post-project conditions[1]. The following documents were relied upon to inform the modeling and design process:

- Engineering Standards and Specifications for Public Improvements, American Canyon Department of Public Works, May 1995.
- BASMAA Post-Construction Manual, Bay Area Stormwater Management Agencies Association, January 2019.
- HEC-HMS Guidance for Flood Control, Unit Hydrograph Method, March 2018
- HEC-HMS Template Model, Flood Control, June 2016
- HYDRO-6 Program Parameters, Flood Control, March 2018
- Mean Seasonal Isohyets Compiled from Precipitation Records (1900-1960), File: isohyetal_cnty, Napa County GIS, January 2011.

Background and Assumptions

For pre-project conditions, the Project site topography (in the proposed development area) has a maximum elevation of approximately 50 feet in the southeast corner and a minimum of approximately 22 feet in the northwest. The post-project grading will utilize this variance to facilitate runoff.

Soil data was obtained from the NRCS's Soil Survey online database. The database stated that the Project area is comprised of three main soils: Haire loam, Haire clay loam, and Clear Lake clay. These soils, characterized by low rates of infiltration, all fall into the NRCS Hydrologic Soil Group "D".

Infiltration rates for pre- and post-project conditions were ascertained from Table 1 of the Flood Control HYDRO-6 Program Parameters. The lower bound of the infiltration rates provided was used due to the "D" Soil Group classification outlined above; a rate of 0.17 inches/hour was assumed for existing conditions, and 0.03 inches/hour was assumed for proposed industrial conditions. For watersheds that contained multiple land use categories a weighted average was calculated.

[1] Based upon Sections 4.02.A and 4.02.C of the City of American Canyon Department of Public Works Engineering Standards and Specifications for Public Improvements Manual, it is our understanding that the Unit Hydrograph Method outlined by the Contra Costa County Flood Control District is the preferred design method for detention basin analyses.

N-values were determined using Figure 1 (for areas less than 200 acres) of the HYDRO-6 Program Parameters; for pre-project areas a value of 0.065 was assumed, characterizing the site as currently undeveloped, and for post-project areas N-values ranging from 0.029 to 0.04 were estimated using the area-based extrapolation method.

The mean annual precipitation (MAP) for the Project area is 20 inches. This value was used in the GHD Devlin Road Analysis and cross-referenced with an isohyet GIS layer available on the Napa County GIS online database. Precipitation falling on the Project footprint currently sheet flows from southwest to northeast where it enters the wetland area and, ultimately, the unnamed tributary to the Napa River.

Facilities Being Modeled

Detention Upstream of Devlin Road

The construction of Devlin Road will impede the flow of water to No Name Creek during large storm events; therefore, to accurately represent the post-development conditions a detention element was included in the model to account for the active storage provided by the elevated roadway during large flow events. Separate storage relationships were developed for the pre- and post-project conditions to assure that any changes in the open space detention volume east of Devlin is accounted for. The stage-storage relationships used in the modeling are included in **Table 1.** Specifics of the culvert design, provided in the Devlin Road Analysis, were used to inform the modeled culvert discharge.

Table 1. Devlin Road Elevation-Storage Relationships

Elevation	Pre-Project Storage	Post-Project Storage	Change in Storage
ft	*acre-feet*	*acre-feet*	*%*
34	0.0	0.0	0
34.5	0.1	0.1	-27
35	0.8	0.6	-24
35.5	2.3	1.7	-27
36	4.9	3.4	-31
36.5	9.4	6.1	-35
37	15.6	9.8	-37

Drainage Management Areas

The proposed design divides the Project area into two drainage management areas (DMAs) comprised of a mix of parking lot, roof area, and pervious landscaping. The tentative mapping shows that the eastern DMA A is 31.4 acres in size while DMA B to the west is 27.2 acres[2]. In conjunction with Flood Control standards, the DMAs are modeled under the industrial land use classification (see **Attachment 1** for model parameters).

[2] Modeled DMA acreages shown in Attachment 1 and Figure 1 are slightly larger than what is provided in the tentative mapping to comply with peak flow modeling requirements; in contrast to water quality, peak flow modeling in HMS requires that rain falling on the footprints of stormwater management facilities is accounted for in basin sizing and flow reduction.

Stormwater Facilities

To meet the flood control requirement outlined by the City of American Canyon in their Engineering Standards and Specifications Manual (post-project peak flows must be reduced to 90% of the pre-project peak) three detention basins are proposed on site. DMA A will have two detention basins and a dedicated bioretention area for water quality, while DMA B will be serviced by one basin sized to comply with both flood control and water quality treatment standards. The bioretention facilities were sized based on the "4% Rule" outlined in the BASMAA Post-Construction Manual. Furthermore, detention basins and bioretention facilities will also be designed to comply with the 2-year hydromodification requirement required for the regional MS4 permit.

Model and Calculation Parameters

To assess the performance of the proposed stormwater facilities during large storm events, a hydrologic model was developed using the U.S. Army Corps of Engineers' HEC-HMS software and modeling protocols outlined in Flood Control's HEC-HMS Guidance Manual.

Input parameters for the HEC-HMS model were compiled from site-specific topography and precipitation information, preliminary Project plans, soil survey information, and additional input recommendations from Flood Control's HEC-HMS Guidance Manual. **Attachment 1** shows land use parameters that were used to calculate lag time (in hours) for both modeled conditions.

Model runs were developed for three conditions: existing conditions, existing conditions with the addition of Devlin Road, and the proposed Project conditions (per current CBG design). For the three conditions, model runs were developed for the 2-, 10-, and 100-year design storm recurrence intervals using a 24-hour storm duration[3]. These storm events were based on a mean annual precipitation of 20 inches and design storm coefficients and rainfall totals specified by Flood Control methodology.

Model Results

Prior to assessing the effect of the projected development, it is important to understand how the construction of Devlin Road will change the hydrology of the local watershed at large. **Table 3** shows a comparison of the model results for the watershed prior to, and after, the construction of Devlin Road.

Table 3. Summary of HMS Modeling Results for Devlin Road Construction

Scenario	Peak Flow (cfs)		
	2-yr 24-hour	10-yr 24-hour	100-yr 24-hour
No Development	93	170	354
Devlin Road Only	73	124	229

[3] The 10- and 100- year design storms utilized the Contra Costa County Flood Control 24-hour storm distribution curve with a peak percent runoff of 11.5%, whereas the 2-year storm was modeled using the Flood Control's 21.2% curve. The higher peaking storm distribution was utilized in the smaller storm event to more accurately assess hydromodification requirements.

Based on the modeled conditions, the construction of the roadway reduces the peak flow for the 2-, 10-, and 100-year 24-hour storm events by 22%, 27%, and 35%, respectively. These results are wholly dependent on the construction of Devlin Road: water is detained behind the elevated roadway and metered out through the box culverts. Beyond the nominal increase in impervious area incurred by the surface of the roadway, these results reflect no change in land use from the pre-project, no development condition. When the post-development land use changes are added to the Devlin Road scenario in HMS the results show an increase in peak flow shown below in **Table 4.**

Table 4. Summary of HMS Modeling Results for All Scenarios

Scenario	Peak Flow (cfs)		
	2-yr 24-hour	10-yr 24-hour	100-yr 24-hour
No Development	93	170	354
Devlin Road Only	73	124	229
Post Development	75	128	241

While these results show a net increase in the peak flow after the development of the Project area, it is important to understand what factor is driving this change. Focusing on the results from the project site provides a better understanding of the cause for this increase (see **Table 5**).

Table 5. Summary of HMS Modeling Results for Project Site Only

Scenario	Peak Flow (cfs)		
	2-yr 24-hour	10-yr 24-hour	100-yr 24-hour
Devlin Road Only	23	35	73
Post Development	11	16	38

As indicated by the table above, the proposed stormwater facilities go far beyond the required level of peak flow reduction for the design storm events. These results, when viewed in conjunction with the data in **Table 3**, attest to the impact that the reduced detention behind Devlin Road has on the system at large. The roughly thirty percent decrease at all elevations in the stage-storage relationship (refer back to **Table 1**) creates a scenario where the culvert is experiencing a higher water surface elevation for each storm event, despite a marked reduction in peak flows leaving the project site before and after development.

As **Table 4** indicates, the construction of Devlin Road is predicted to greatly reduce the pre-project peak flow rate as water is backed up to the east of the roadway and metered out through the four 2-foot by 4-foot box culverts. However, through further analysis one can see that this benefit is largely derived from the detention provided by the undeveloped Giovannoni property.

Conclusion

Based upon the outcomes for the three modeled conditions, multiple changes from the pre-project scenario are evident. First off, the construction of Devlin Road will largely constrict the flowrate from the watershed to No Name Creek; the 100-yr discharge drops to 65% of the pre-

project peak flow with the addition of the roadway. Secondly, the peak flow increases to 68% of the pre-project condition for the 100-year storm event after the development of the Project area, but still remains well within the flood control requirements set forth by the City of American Canyon. By viewing this proposed development on the scale of the regional watershed the combined construction of Devlin Road and the Project area will not create adverse effects related to flood control or hydromodification downstream of the development.

1. Refer to Figure 1 for location. Asterisks denote that a shed was changed to comply to changes in project conditions; however, the general location of the sheds are maintained across the scenarios.
2. Contra Costa Flood Control District Methodology Lag Time Equation: 24 x N x (L*Lc / S^0.05)^0.38.
3. A minimum Lag Time of 0.167 hours was assumed during modeling.

Executive Summary

The proposed project includes the construction of 2.2 to 2.4 million square feet of warehouse which would be built concurrently with the planned extension of Devlin Road between Green Island Road and South Kelly Road in the City of American Canyon. This project is expected to generate an average of 3,888 equivalent passenger car trips per day, including 240 trips during the a.m. peak hour, and 264 during the p.m. peak hour.

The study area for the operational analysis includes the intersections of Devlin Road/South Kelly Road, Devlin Road/Green Island Road and Paoli Loop Road/Green Island Road. Analysis indicates that the unsignalized intersections operate acceptably under Existing Conditions and would continue to do so under Future Conditions and upon the addition of project-related traffic volumes. SR 29/South Kelly Road would operate at LOS F under Future Conditions without or with the project, but this operation was considered acceptable since the intersection is exempt from the City's LOS standard and Caltrans has no operational standard. As required by the City in their Traffic Impact Fee Program, the project should pay a fee toward the cost of the planned future improvements to SR 29 to address cumulative effects of project traffic.

Although the project would be expected to have a less-than-significant transportation impact on vehicle miles traveled (VMT), the implementation of TDM measures such as use of ridesharing, offering secure bicycle parking, and educational materials would further lower the anticipated project VMT and are therefore recommended.

The project includes the addition of sidewalks along the Devlin Road extension and a multi-modal path along Green Island Road in the area adjacent to the project. Bicycle facilities serving the project site are generally adequate, though space should be provided for bicycles to be stored on-site. The project includes an extension to the Napa Valley Vine Trail along Delvin Road which improves local and regional bicycle connectivity. Existing transit stops are not within the immediate vicinity of the site. This is typical for this area and is therefore considered an acceptable condition.

Vehicles would access the project via multiple driveways on Green Island Road and the future Devlin Road extension. Sight distances at the project driveways for both entering and exiting drivers is expected to be adequate assuming placement of buildings, signs and landscaping are outside the areas needed for clear lines of sight. Assuming a maximum project size of 2.4 million square feet, City Code requires a minimum of 1,230 parking spaces should be provided.

Introduction

This report presents an analysis of the potential traffic impacts that would be associated with the proposed development of 2.2 to 2.4 million square feet of warehouse space between Green Island Road and Devlin Road in the area west of SR 29 in the City of American Canyon. The traffic study was completed in accordance with the criteria established by the City of American Canyon and is consistent with standard traffic engineering techniques.

Prelude

The purpose of a traffic impact study is to provide City staff and policy makers with data that they can use to make an informed decision regarding the potential traffic impacts and effects on traffic operation of a proposed project, and any associated improvements that would be required in order to mitigate these impacts and effects to an acceptable level under CEQA, the City's General Plan, or other policies. Impacts relative to access for pedestrians, bicyclists, and to transit are addressed in the context of the CEQA criteria. Consistent with SB 743, the project's transportation impacts were analyzed using VMT. While no longer a part of the CEQA review process, vehicular traffic service levels at key intersections were evaluated for consistency with General Plan policies by determining the number of new trips that the proposed use would be expected to generate, distributing these trips to the surrounding street system based on anticipated travel patterns specific to the proposed project, then analyzing the impact the new traffic would be expected to have on the study intersections.

Project Profile

The project as proposed includes 2.2 to 2.4 million square feet of high cube warehouse space. The site is situated between Green Island Road and Devlin Road in the area west of SR 29 in the City of American Canyon and would be accessible from either roadway. Approximate boundaries of the site are illustrated in Figure 1.

Traffic Study for the Giovannoni Logistics Center

Figure 1 – Study Area and Lane Configurations

W-Trans

Transportation Setting

Operational Analysis

Study Area and Periods

The study area consists of the following intersections selected through consultation from City staff:

1. SR 29/South Kelly Road
2. Devlin Road/South Kelly Road
3. Devlin Road/Green Island Road (Future Intersection)
4. Paoli Loop Road/Green Island Road

Operating conditions during the weekday a.m. and p.m. peak periods were evaluated to capture the highest potential impacts for the proposed project as well as the highest volumes on the local transportation network. The morning peak hour occurs between 7:00 and 9:00 a.m. and reflects conditions during the home to work or school commute, while the p.m. peak hour occurs between 4:00 and 6:00 p.m. and typically reflects the highest level of congestion during the homeward bound commute.

Study Intersections

SR 29/South Kelly Road is a signalized four-legged intersection with protected left turns on all approaches. There are crosswalks on the west, north and east legs.

Devlin Road/South Kelly Road is an all-way stop-controlled intersection with crosswalks on the east and south legs.

Devlin Road/Green Island Road (Future) is a future tee intersection with stop control on the southbound Devlin Road approach. Crosswalks are planned at the north leg.

Paoli Loop Road/Green Island Road is a tee intersection with stop control on the northbound Paoli Loop Road approach. There are no crosswalks.

The locations of the study intersections and the existing lane configurations and controls are shown in Figure 1.

Collision History

The collision history for the study area was reviewed to determine any trends or patterns that may indicate a safety issue. Collision rates were calculated based on records available from the California Highway Patrol as published in their Statewide Integrated Traffic Records System (SWITRS) reports. The most current five-year period available is October 1, 2015 through September 30, 2020.

As presented in Table 1, the calculated collision rates for the study intersections were compared to average collision rates for similar facilities statewide, as reported in the publication *2016 Collision Data on California State Highways*, California Department of Transportation (Caltrans). These average rates statewide are for intersections in the same environment (urban, suburban, or rural), with the same number of approaches (three or four), and the same controls (all-way stop, two-way stop, or traffic signal). A more detailed evaluation is provided for study intersections where the collision rates were higher than the statewide average. The collision rate calculations are provided in Appendix A.

Table 1 – Collision Rates for the Study Intersections			
Study Intersection	**Number of Collisions (2015-2020)**	**Calculated Collision Rate (c/mve)**	**Statewide Average Collision Rate (c/mve)**
1. SR 29/South Kelly Road	48	**0.82**	0.58
2. Devlin Road/South Kelly Road	2	0.32	0.55
3. Devlin Road/Green Island Road [1]	-	-	-
4. Paoli Loop Road/Green Island Road	2	**0.20**	0.16

Note: c/mve = collisions per million vehicles entering
[1] Collision rate was not evaluated at this future intersection

Of the 48 reported collisions that occurred at the intersection of SR 29/South Kelly Road, 30 were rear-end collisions with the primary cause being unsafe speeds. This type of crash is common at signalized intersections where there is congestion, especially during peak periods. Because of the regional nature of the traffic that causes the congestion, and as this location is under the jurisdiction of Caltrans, there is little that the City can do to address this condition though increased enforcement and analysis of the potential to improve signal timing to reduce congestion could be requested of the Highway Patrol and Caltrans, respectively.

The collision rate at Paoli Loop Road/Green Island Road is higher than the statewide average, with one of the two reported collisions being a head-on collision and the other being a broadside collision. The broadside collision resulted from "traffic signal and sign" violations, and the head-on collision was attributed to unsafe speed. With no clear pattern and given the very low number of crashes, no remedial actions are apparent.

Alternative Modes

Pedestrian Facilities

Pedestrian facilities include sidewalks, crosswalks, pedestrian signal phases, curb ramps, curb extensions, and various streetscape amenities such as lighting, benches, etc. In general, sidewalk coverage is limited in the area surrounding the project site. Existing gaps and obstacles along the connecting roadways impact convenient and continuous access for pedestrians and present safety concerns in those locations where appropriate pedestrian infrastructure would address potential conflict points. Within the study area, new sidewalks are planned along the future extension of Devlin Road.

Bicycle Facilities

The *Highway Design Manual*, Caltrans, 2017, classifies bikeways into four categories:

- **Class I Multi-Use Path** – a completely separated right-of-way for the exclusive use of bicycles and pedestrians with cross flows of motorized traffic minimized.
- **Class II Bike Lane** – a striped and signed lane for one-way bike travel on a street or highway.
- **Class III Bike Route** – signing only for shared use with motor vehicles within the same travel lane on a street or highway.
- **Class IV Bikeway** – also known as a separated bikeway, a Class IV Bikeway is for the exclusive use of bicycles and includes a separation between the bikeway and the motor vehicle traffic lane. The separation may include, but is not limited to, grade separation, flexible posts, inflexible physical barriers, or on-street parking.

In the project area, Class II bike lanes exist on Devlin Road between Middleton Way and South Kelly Road. Bicyclists ride in the roadway and/or on sidewalks along all other streets within the project study area. Table 2 summarizes

the existing and planned bicycle facilities in the project vicinity as contained in the *Napa Countywide Bicycle Plan*, Napa Valley Transportation Authority, 2019.

Table 2 – Bicycle Facility Summary

Status Facility	Class	Length (miles)	Begin Point	End Point
Existing				
Devlin Road	II	0.09	Middleton Way	South Kelly Road
Planned				
S Kelly Rd	I	0.20	SR 29	Devlin Rd
Vine Trail (along Devlin Rd)	I	1.62	Middleton Way	Watson Ln
Green Island Rd	I	0.33	Vine Trail	Commerce Blvd
Green Island Rd	II	0.25	Northern Intersection of Green Island Rd and Mezzetta Ct	Vine Trail

Source: *Napa Countywide Bicycle Plan*, Napa Valley Transportation Authority, 2019

Transit Facilities

Valley Intercity Neighborhood Express (VINE) Transit provides fixed route bus service throughout Napa County. American Canyon Transit (ACT) is an on-demand, door-to-door, transit service for persons with disabilities who cannot independently use regular fixed-route transit services. Neither VINE nor ACT maintains stops near the project site.

On-demand private taxi services are available in the study area 24 hours a day. Taxis can be used for trips within the local Planning Area and farther destinations, including nearby airports. Other ride-hailing applications are also available in study area and provide transportation throughout the Bay Area.

Capacity Analysis

Intersection Level of Service Methodologies

Level of Service (LOS) is used to rank traffic operation on various types of facilities based on traffic volumes and roadway capacity using a series of letter designations ranging from A to F. Generally, Level of Service A represents free flow conditions and Level of Service F represents forced flow or breakdown conditions. A unit of measure that indicates a level of delay generally accompanies the LOS designation.

The study intersections were analyzed using methodologies published in the *Highway Capacity Manual* (HCM), 6th Edition, Transportation Research Board, 2018. This source contains methodologies for various types of intersection control, all of which are related to a measurement of delay in average number of seconds per vehicle.

The Levels of Service for the intersections with side street stop controls, or those which are unsignalized and have one or two approaches stop controlled, were analyzed using the "Two-Way Stop-Controlled" intersection capacity method from the HCM. This methodology determines a level of service for each minor turning movement by estimating the level of average delay in seconds per vehicle. Results are presented for individual movements together with the weighted overall average delay for the intersection.

The study intersections with stop signs on all approaches were analyzed using the "All-Way Stop-Controlled" Intersection methodology from the HCM. This methodology evaluates delay for each approach based on turning movements, opposing, and conflicting traffic volumes, and the number of lanes. Average vehicle delay is computed for the intersection as a whole and then related to a Level of Service.

The study intersections that are currently controlled by a traffic signal, or may be in the future, were evaluated using the signalized methodology from the HCM. This methodology is based on factors including traffic volumes, green time for each movement, phasing, whether the signals are coordinated or not, truck traffic, and pedestrian activity. Average stopped delay per vehicle in seconds is used as the basis for evaluation in this LOS methodology. For purposes of this study, delays were calculated using signal timing obtained from Caltrans.

The ranges of delay associated with the various levels of service are indicated in Table 3.

Table 3 – Intersection Level of Service Criteria			
LOS	**Two-Way Stop-Controlled**	**All-Way Stop-Controlled**	**Signalized**
A	Delay of 0 to 10 seconds. Gaps in traffic are readily available for drivers exiting the minor street.	Delay of 0 to 10 seconds. Upon stopping, drivers are immediately able to proceed.	Delay of 0 to 10 seconds. Most vehicles arrive during the green phase, so do not stop at all.
B	Delay of 10 to 15 seconds. Gaps in traffic are somewhat less readily available than with LOS A, but no queuing occurs on the minor street.	Delay of 10 to 15 seconds. Drivers may wait for one or two vehicles to clear the intersection before proceeding from a stop.	Delay of 10 to 20 seconds. More vehicles stop than with LOS A, but many drivers still do not have to stop.
C	Delay of 15 to 25 seconds. Acceptable gaps in traffic are less frequent, and drivers may approach while another vehicle is already waiting to exit the side street.	Delay of 15 to 25 seconds. Drivers will enter a queue of one or two vehicles on the same approach and wait for vehicle to clear from one or more approaches prior to entering the intersection.	Delay of 20 to 35 seconds. The number of vehicles stopping is significant, although many still pass through without stopping.
D	Delay of 25 to 35 seconds. There are fewer acceptable gaps in traffic, and drivers may enter a queue of one or two vehicles on the side street.	Delay of 25 to 35 seconds. Queues of more than two vehicles are encountered on one or more approaches.	Delay of 35 to 55 seconds. The influence of congestion is noticeable, and most vehicles have to stop.
E	Delay of 35 to 50 seconds. Few acceptable gaps in traffic are available, and longer queues may form on the side street.	Delay of 35 to 50 seconds. Longer queues are encountered on more than one approach to the intersection.	Delay of 55 to 80 seconds. Most, if not all, vehicles must stop, and drivers consider the delay excessive.
F	Delay of more than 50 seconds. Drivers may wait for long periods before there is an acceptable gap in traffic for exiting the side streets, creating long queues.	Delay of more than 50 seconds. Drivers enter long queues on all approaches.	Delay of more than 80 seconds. Vehicles may wait through more than one cycle to clear the intersection.

Reference: *Highway Capacity Manual,* 6th Edition, Transportation Research Board, 2018

Traffic Operation Standards

City of American Canyon

The *City of American Canyon General Plan Circulation Element* specifies minimum level-of-service standards for all streets and intersections in the City's jurisdiction. In section 4.1.6, the City establishes the following performance standards for acceptable LOS:

Achieve and maintain a Multimodal LOS D or better for roadways and intersections during peak hours where possible for as long as possible. However, recognizing that LOS D may not be achievable or cannot be maintained upon full buildout of the General Plan, due to traffic generated from sources beyond control of the City, the City Council shall have the discretion to only require feasible mitigation measures that may not achieve LOS D, but will reduce the impact of any development use or VMT planned for in the Land Use Element of the General Plan.

The locations that may not achieve or maintain LOS D are as follows and will be exempt from the LOS D policy:

- *State Route 29 through the City*
- *American Canyon Road from SR 29 to Flosden Road-Newell Drive*
- *Flosden Road south of American Canyon Road*

Caltrans

The study intersection of SR 29/South Kelly Road is located on the State Transportation Network (STN) and is therefore under jurisdiction of Caltrans. It is noted that Caltrans does not currently have a standard of significance relative to intersection operation as this is no longer a CEQA issue. The new vehicle miles traveled-focused Transportation Impact Study Guide (TISG), published in May 2020, replaced the Guide for the Preparation of Traffic Impact Studies, 2002. As indicated in the TISG, the Department is transitioning away from requesting LOS or other vehicle operations analyses of land use projects and will instead focus on Vehicle Miles Traveled (VMT).

Existing Conditions

The Existing Conditions scenario provides an evaluation of current operation based on existing traffic volumes during the a.m. and p.m. peak hours. This condition does not include project-generated traffic volumes. Volume data was collected on various dates in February, May and November 2019 while local schools were in session and prior to the outbreak of COVID-19 and the resulting change in travel patterns. It is noted that travel patterns within American Canyon vary between the a.m. and p.m. peak hours and individual drivers may use different routes for their morning and evening commutes. Copies of the traffic count data sheets are provided in Appendix B.

Intersection Levels of Service

Under existing conditions, all study intersections are operating acceptably during both peak hours evaluated. The existing traffic volumes are shown in Figure 2. A summary of the intersection Level of Service calculations is contained in Table 4, and copies of the calculations are provided in Appendix C.

Table 4 – Existing Peak Hour Intersection Levels of Service

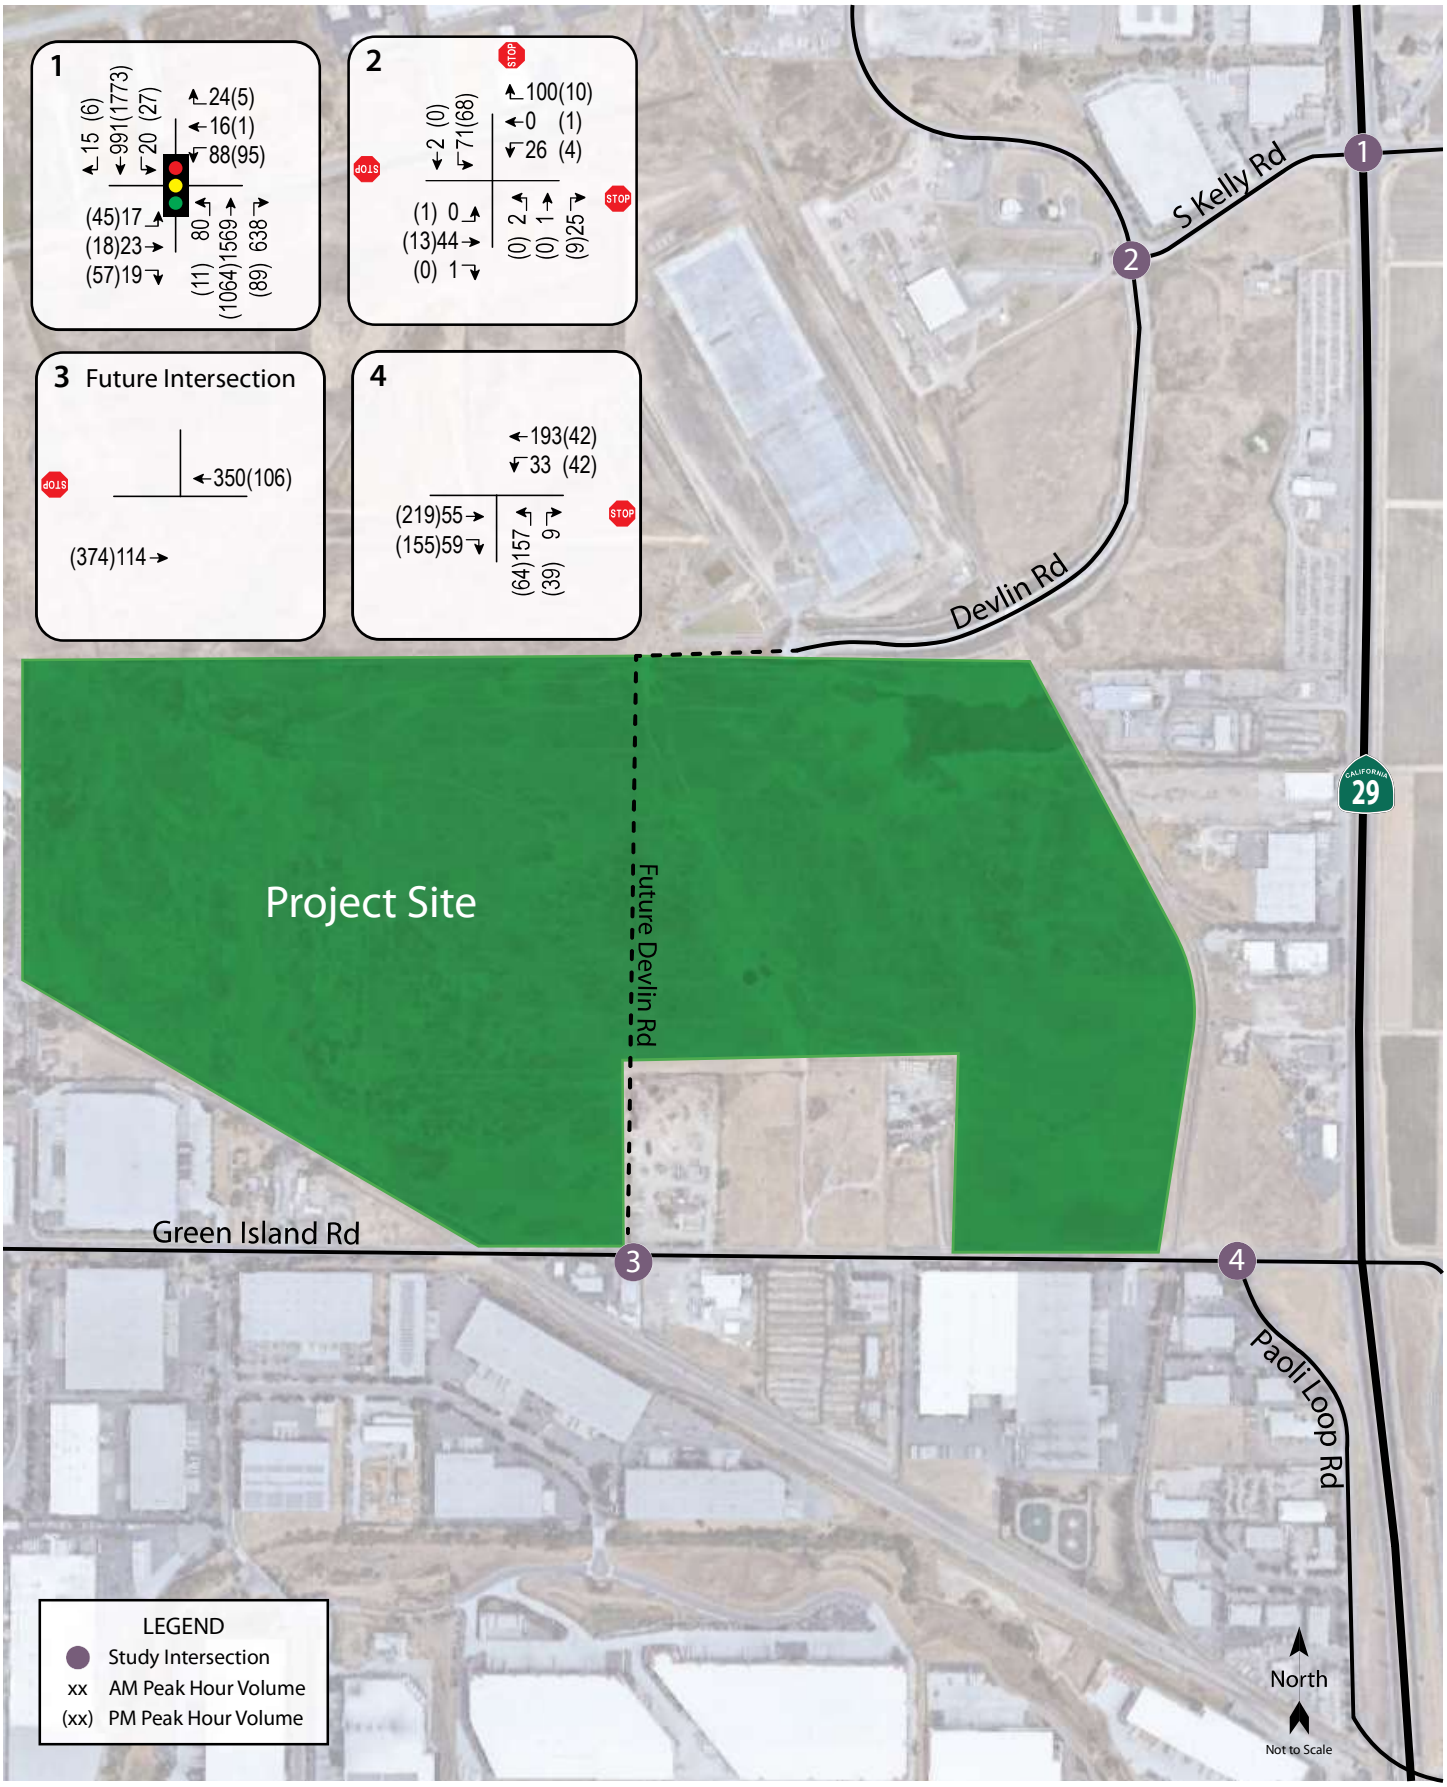
Study Intersection ***Approach***	AM Peak		PM Peak	
	Delay	**LOS**	**Delay**	**LOS**
1. SR 29/S Kelly Rd	34.6	C	15.9	B
2. Devlin Rd/S Kelly Rd	7.8	A	8.0	A
3. Devlin Rd/Green Island Rd [1]	-	-	-	-
Southbound (Devlin Rd) Approach	-	-	-	-
4. Paoli Loop Rd/Green Island Rd	4.9	A	3.1	A
Northbound (Paoli Loop) Approach	*13.3*	*B*	*13.5*	*B*

Notes: Delay is measured in average seconds per vehicle; LOS = Level of Service; Results for minor approaches to two-way stop-controlled intersections are indicated in *italics*

[1] Level of Service was not evaluated at this future intersection

Future Conditions

Future (2040) a.m. and p.m. peak hour volume projections for SR 29/South Kelly Road were derived from a build-out analysis which is contained in the *Napa Junction III Transportation Impact Analysis Report,* Omni-Means, LTD,



aca033.ai 4/21

Traffic Study for the Giovannoni Logistics Center

Figure 2 – Existing Traffic Volumes

W-Trans

2011; this scenario represents cumulative traffic conditions that would be expected upon build out of the land uses identified in the *General Plan*. Although some of the anticipated development included in this previous effort

may already be complete and occupied, to provide a conservative estimate of future operation the incremental increase in trips associated with build out of the City of American Canyon under its current *General Plan* was added to current volumes to determine Future (year 2040) operating conditions without the project. A growth rate was then created for the intersection of SR 29/South Kelly Road based on the volumes for this location in the *Napa Junction III Transportation Impact Analysis Report*.

Because the west side of SR 29 is already nearly built out other than the project site, so would be expected to experience considerably less of an increase in traffic compared to SR 29, a growth rate of one-percent per year was used to develop future a.m. and p.m. peak hour volumes for the study intersections located west of SR 29.

Under the anticipated Future volumes, the study intersections are expected to operate acceptably during the a.m. and p.m. peak hours except for SR 29/South Kelly Road, which is expected to operate at LOS F during both peak hours. Future volumes are shown in Figure 3 and operating conditions are summarized in Table 5.

Table 5 – Future Peak Hour Intersection Levels of Service

Study Intersection *Approach*	AM Peak		PM Peak	
	Delay	LOS	Delay	LOS
1. SR 29/S Kelly Rd	107.4	F	84.3	F
2. Devlin Rd/S Kelly Rd	8.0	A	8.0	A
3. Devlin Rd/Green Island Rd [1]	-	-	-	-
Southbound (Devlin Rd) Approach	-	-	-	-
4. Paoli Loop Rd/Green Island Rd	5.2	A	3.1	A
Northbound (Paoli Loop) Approach	*14.3*	*B*	*13.4*	*B*

Notes: Delay is measured in average seconds per vehicle; LOS = Level of Service; Results for minor approaches to two-way stop-controlled intersections are indicated in *italics*

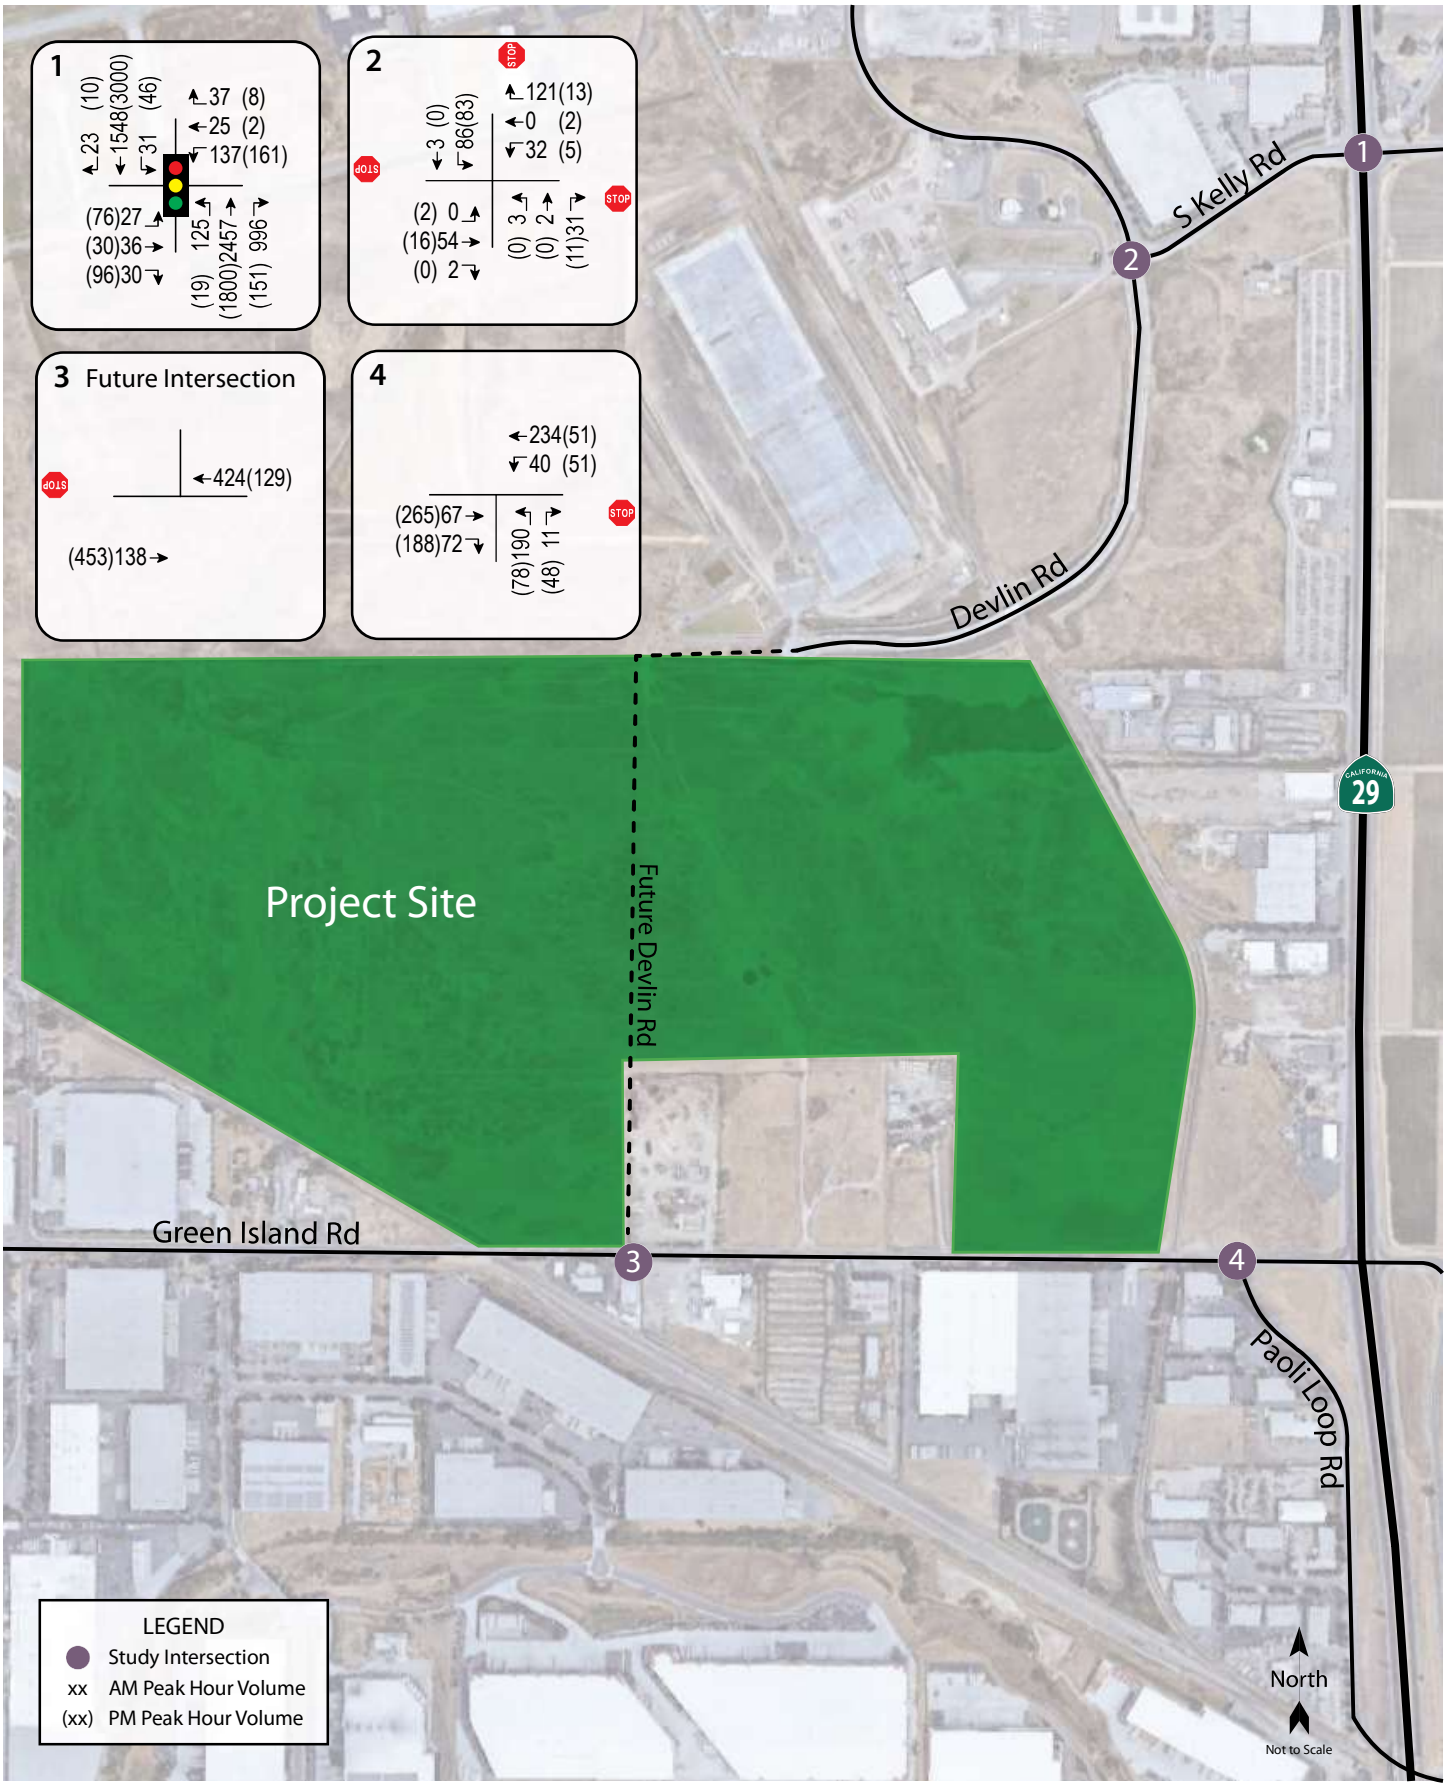
[1] Level of Service was not evaluated at this future intersection

While the intersection of SR 29/South Kelly Road is projected to operate at LOS F during each peak hour, this operation was considered acceptable since SR 29 is exempt from the City's LOS standard and Caltrans no longer applies an LOS standard. The *City of American Canyon – Broadway District Specific Plan Draft EI*R, First Carbon Solutions, 2017, states that there are future plans for SR 29 to have three through lanes in each direction through American Canyon. Because funding has not been identified for this capacity enhancement, it was conservatively assumed that the current configuration with only two through lanes in each direction would remain, and this configuration was used for the analysis.

Furthermore, the future year analysis results for facilities along SR 29 (specifically, the intersection of SR 29/South Kelly Road) is deemed to be more conservative than what was presented for this intersection in the *Watson Ranch Specific Plan Environmental Impact Report* (September 2018) which indicated LOS C and D operation for the a.m. and p.m. peak hours, respectively.

Project Description

The project includes the construction of 2.2 to 2.4 million square feet of warehouse which would be built concurrently with the planned extension of Devlin Road between Green Island Road and South Kelly Road in



aca033.ai 4/21

Traffic Study for the Giovannoni Logistics Center

Figure 3 – Future Traffic Volumes

American Canyon. It should be noted that the extension of Devlin Road is identified in the City's General Plan as a circulation improvement and its completion would have been pursued by the City with or without the involvement of this project. The project would be completed in two phases. Phase 1 includes the construction of the Devlin Road extension and two warehouse buildings along with supporting surface parking lots and circulating roads on the east side of the Devlin Road extension. A supply of 858 parking spaces is presently planned for Phase 1. Phase 2 would consist of three or four warehouse buildings and supporting parking lots and circulating roads to the west of the Devlin Road extension.

The extension of Devlin Road would be approximately 3,000 feet long and include bicycle lanes and a sidewalk along its eastern edge. The project also includes the construction of a multi-modal path along the northern side of Green Island Road at the project frontage.

The proposed project site plan for Phase 1 is shown in Figure 4. A site plan for Phase 2 is currently being developed and was not available for use in this study.

Trip Generation

The anticipated trip generation for the proposed project was estimated using standard rates published by the Institute of Transportation Engineers (ITE) in *Trip Generation Manual*, 10th Edition, 2017 for a "High-Cube Transload and Short-Term Storage Warehouse" (Land Use #154). The project would be comprised of multiple warehouse buildings with a combined size of between 2.2 and 2.4 million square feet. To be conservative, the maximum size of 2.4 million square feet was used to estimate the trip generation. The project is not anticipated to generate any internal capture trips, pass-by trip credits or any other trip reductions. The number of truck trips associated with a High-Cube Warehouse was estimated using rates published in the *Trip Generation Manual* and validated using local vehicle classification counts conducted in June 2021. Copies of the counts and truck percentage derivation are provided in Appendix B.

As shown in Table 6, the project is expected to generate an average of 3,888 net-new passenger car equivalent trips per day, including 240 trips during the a.m. peak hour and 264 during the p.m. peak hour. These new trips represent the increase in traffic associated with the project compared to existing volumes. To account for the effect of heavy vehicles (such as tractor trucks), a heavy vehicle adjustment factor was applied to convert truck trips to an equivalent passenger car trip total. The passenger car equivalency factor (PCE) for heavy vehicles is assumed to be 2.0 (i.e., each tractor truck has the effect of two passenger cars due to longer start up times at intersections and when making turns). Thus, the number of truck trips per hour was multiplied by 2.0 to determine the equivalent passenger car trips per hour.

Table 6 – Trip Generation Summary

Land Use	Units	Daily		AM Peak Hour				PM Peak Hour			
		Rate	Trips	Rate	Trips	In	Out	Rate	Trips	In	Out
High-Cube Warehouse	2,400 ksf										
Vehicles (Trucks + Pass. Cars)		1.40	3,360	0.08	192	148	44	0.10	240	67	173
Trucks		0.22	528	0.02	48	37	11	0.01	24	7	17
Pass. Cars		-	*2,832*	-	*144*	*111*	*33*	-	*216*	*60*	*156*
Trucks (pass. car equivalents)		-	*1,056*	-	*96*	*74*	*22*	-	*48*	*14*	*34*
Total Passenger Car Trips			**3,888**		**240**	**185**	**55**		**264**	**74**	**190**

Note: ksf = 1,000 square feet, Total Passenger Car Trips = Passenger Cars plus Passenger Car Equivalent Units of Trucks

Traffic Study for the Giovannoni Logistics Center

Figure 4 – Site Plan

Trip Distribution

The pattern used to allocate new project trips to the street network was determined by reviewing likely routes for employees, visitors, and deliveries. The directionality experienced on SR 29 during the morning and evening commute periods was considered in developing the proposed assumptions. Based on the assumptions shown in Table 7, the following distribution was applied. Project traffic volumes are shown in Figure 5.

Table 7 – Trip Distribution Assumptions

Route	AM		PM	
	Percent	Trips	Percent	Trips
To/from North on SR 29	50%	120	55%	145
To/from South on SR 29	50%	120	45%	119
TOTAL	**100%**	**240**	**100%**	**264**

Intersection Operation

Existing plus Project Conditions

Upon the addition of project-related traffic to the Existing volumes, all study intersections are expected to continue operating at LOS C or better. These results are summarized in Table 8. Existing plus Project traffic volumes are shown in Figure 6.

Table 8 – Existing and Existing plus Project Peak Hour Intersection Levels of Service

	Study Intersection *Approach*	Existing Conditions				Existing plus Project			
		AM Peak		PM Peak		AM Peak		PM Peak	
		Delay	LOS	Delay	LOS	Delay	LOS	Delay	LOS
1.	SR 29/S Kelly Rd	34.6	C	15.9	B	34.7	C	16.7	B
2.	Devlin Rd/S Kelly Rd	7.8	A	8.0	A	8.4	A	7.9	A
3.	Devlin Rd/Green Island Rd	-	-	-	-	0.5	A	1.4	A
	Southbound (Devlin Rd) Approach	-	-	-	-	*12.1*	*B*	*12.7*	*B*
4.	Paoli Loop Rd/Green Island Rd	4.9	A	3.1	A	7.5	A	4.0	A
	Northbound (Paoli Loop) Approach	*13.3*	*B*	*13.5*	*B*	*17.9*	*C*	*18.1*	*C*

Notes: Delay is measured in average seconds per vehicle; LOS = Level of Service; Results for minor approaches to two-way stop-controlled intersections are indicated in *italics*

Finding – The study intersections are anticipated to operate at LOS C or better with project-generated traffic added.

Future plus Project Conditions

Upon the addition of project-generated traffic to the anticipated Future volumes, all unsignalized study intersections are expected to operate acceptably. SR 29/South Kelly Road would continue to operate at LOS F during both peak hours. Future plus Project traffic volumes are shown in Figure 7 and operating conditions are summarized in Table 9.

Notes: Delay is measured in average seconds per vehicle; LOS = Level of Service; Results for minor approaches to two-way stop-controlled intersections are indicated in *italics*

As mentioned previously, there are future plans for SR 29 to have three travel lanes in each direction through American Canyon. As required by the City in their Traffic Impact Fee Program, the project should pay a proportional share fee toward the cost of this planned future infrastructure improvement. As specific building projects move forward, each should contribute to the funds needed for the planned improvements to SR 29 based on the City's fee schedule.

Finding – The study intersections will continue operating acceptably with project traffic added, with the exception of SR 29/South Kelly Road, which would operate at LOS F with or without the addition of project traffic, though the project's effect would be considered acceptable since SR 29 is exempt from the City's LOS standard.

Recommendation – As required by the City in their Traffic Impact Fee Program, the project should pay a fee toward the cost of the planned future improvements to SR 29.

Vehicle Miles Traveled

Senate Bill (SB) 743 established a change in the metric to be applied for determining traffic impacts associated with development projects. Rather than the delay-based criteria associated with a Level of Service analysis, the increase in Vehicle Miles Traveled (VMT) because of a project will be the basis for determining impacts. The City of American Canyon has not yet established thresholds of significance related to VMT. The Napa County travel demand model is not currently available for use as a source for VMT analysis. In lieu of an established local methodology, the project-related VMT impacts were quantitatively assessed based on guidance provided by the California Governor's Office of Planning and Research (OPR) in the publication *Transportation Impacts (SB 743) CEQA Guidelines Update and Technical Advisory*, 2018 and approved by City of American Canyon staff.

Based on a review of established policies currently used by OPR, Sacramento County and the City of San Jose, a VMT impact would be identified at an industrial project if the project VMT per employee is higher than the regional average VMT per employee. For this study, the regional average VMT is defined as the nine county Bay Area average. As reported by the City of Vallejo in their *CEQA Transportation Impact Analysis Guidelines* (dated October 2020), the Nine-County Bay Area Average VMT per employee is 23.00 miles per employee. According to Statewide Travel Demand Model estimates, this project is located within a Traffic Analysis Zone (TAZ) with a projected VMT per employee of 16.24 miles. Because this per capita VMT rate is lower than the significance threshold of 23.0 miles, the project would be considered to have a less-than-significant VMT impact. A summary of the VMT findings is provided in Table 10.

Table 10 – Vehicle Miles Traveled Analysis Summary

VMT Metric	Regional Average/ Significance Threshold	Project VMT Rate	Resulting Significance
Employment VMT per Capita	23.00	16.24	Less-Than-Significant

Note: VMT Rate is measured in VMT/Capita, or the number of daily miles driven per employee

Finding – The project would be expected to have a less-than-significant transportation impact on vehicle miles traveled.

Transportation Demand Management (TDM) Measures

The following section describes a potential Transportation Demand Management (TDM) program for employees of the logistics center. While the project's potential impact is expected to be less than significant, implementation of a TDM program would potentially lower the vehicle miles traveled associated with this project and thus have a regional benefit.

According to SB 1128, adopted in 2016, all employers with 50 or more full-time employees within the nine-county Bay Area are subject to SB 1128, which requires employers to offer their employees one of four options – pre-tax benefits, transit or vanpool subsidies, employer-provided transit, or an alternative benefit of equal effectiveness. The following TDM program would fulfill this legislative requirement.

Ridesharing Program

Carpooling is one of the most common and cost-effective alternative modes of transportation and one that commuters can adopt part-time. Given the delivery station's auto-oriented location, it can also be one of the most effective alternatives to driving alone. There are numerous benefits to ridesharing. Carpooling can reduce peak-period vehicle trips and increase commuters' travel choices. Further, it reduces congestion, road and parking facility costs and pollution emissions. Carpooling tends to have the lowest cost per passenger-mile of any

motorized mode of transportation since it makes use of a vehicle seat that would otherwise be empty. Carpooling also provides financial savings for the consumer by decreasing fuel and parking costs. Financial incentives can be an effective way to encourage employees to carpool. The tenant should provide a monetary incentive to employees who agree to carpool to work a minimum of 50 percent of the time. This program should be offered to all employees of the project.

Ridematching

The greatest barrier to workplace carpooling is often simply being able to identify and travel with other employees who live nearby. There are many services that can assist in pairing employees within the same organization or across organizations. The most basic publicly available service is 511.org's free ridematching service, *Merge*. There are also various private ridematching providers (e.g. Zimride, RideAmigos, Via, Scoop) that can effectively create carpool networks while making them safe and convenient for their users. Information on a variety of programs is offered through 511.org.

Recommendation: The tenant should market the *Merge* program to employees and assist on an as-needed basis with ridematching questions or concerns. A monetary incentive may also be offered to employees who carpool to and from work.

Vanpooling

Employer-provided vans can provide several advantages. Vans are defined as vehicles able to carry at least six adults and can reduce the cost of commuting for employees by removing the need for workers to put mileage on their own vehicles and, depending on the level of subsidy, they may not need to pay for gas. For tax purposes, employers may be able to deduct the costs of vans as a "qualified transportation fringe benefit."

Recommendation: The tenant should market the vanpool program to all employees. Identify which employees would be the most suitable to participate in vanpools based on their home locations and reach out directly to those employees to determine if vanpools of at least six persons each are feasible. If so, provide one or more fully subsidized vans for those employees with the condition that they must use it for their commute.

Priority Parking

An easy way of promoting ridesharing is to designate priority employee parking spaces for carpools and vanpools. The cost of this improvement is limited to the paint or sign used and can help market ridesharing as a priority in the organization.

Recommendation: Up to five parking spaces for rideshare vehicles should be designated on the plans for the project.

Electric Vehicle Charging Stations

While the provision of dedicated parking for Electric Vehicles (EVs) and charging stations do not result in trip or VMT reductions, they can help reduce the total GHG emissions of a project.

Recommendation: Electric vehicle parking stalls and charging stations consistent with California Green (Cal Green) building standards should be provided for each building.

Guaranteed Ride Home (GRH)

Guaranteed Ride Home (GRH) is a program that provides a "back-up" ride to employees who use transit, carpool, biking/walking, or other alternatives as their commute mode; in Napa County, it is provided by the NVTA via their V-Commute Program. If an employee who carpools to work, so does not have their own vehicle, needs to leave work for an emergency, such as a sick child or other unexpected need, they will be redeemed for up to four GRH

trips per calendar year. This is an important supportive measure to encourage employees to not drive alone to work and often goes as a welcome, but unused benefit.

Recommendation: The tenant should market the GRH program to employees and assist with sign-ups as needed.

Bicycle Benefits

Bicycle Parking and Maintenance Tools

The provision of both short-term and long-term bicycle parking is important. Secure long-term parking (e.g. bike lockers) is a critical component in encouraging employees to bike to work as the lack of secure parking is often cited by employees as a deterrent. Short-term parking (e.g. bike racks) can be used by employees or visitors.

In addition to providing bicycle parking, some businesses are now encouraging bicycle use by providing employees with the basic tools necessary to maintain their bicycles and on-site shower and clothes locker facilities. Often, these tools can be kept in bicycle storage areas and include simple items such as a bike pump and tire patches that are essential for bike travel, but also inexpensive.

Financial incentives can also be an effective way to encourage employees to ride a bicycle to reach the site. In addition to those who carpool, the applicant should provide a monetary incentive to employees who agree to walk or bicycle to work a minimum of 50 percent of the time.

Recommendation: The tenant should provide both short-term and long-term bicycle parking as well as basic bicycle maintenance tools and on-site shower facilities. Offer a monetary incentive to employees who walk or ride a bicycle to work.

Education, Outreach & Marketing

Welcome Packet for New Employees

New employees should be provided with a welcome packet containing relevant transportation information. The packet should include information on all available TDM measures as well as information from Vine Transit, the Napa County Bicycle Coalition and material regarding 511.org ride-matching services.

Monitor Performance

It is important to continually monitor the performance of a TDM program and adjust measures as necessary to ensure its success. The tenant should conduct mode split and vehicle miles traveled (VMT) surveys each year both to determine if adjustments are needed and to use as marketing material. Employee satisfaction surveys are also an effective way of ensuring a quality TDM program.

Transportation Coordinator

The presence of a staff person dedicated part-time to overseeing and managing the TDM program would be helpful in ensuring the ongoing success of these programs. This would not be a distinct position, but instead would be a role that is integrated into the duties of an on-site manager. The duties can include:

- Create and distribute resident transportation information welcome packets
- Maintain and update the transportation information kiosk board
- Distribute Napa Bicycle Coalition maps
- Monitor bicycle parking to ensure that there is sufficient space
- Assist in selling or distributing transit passes
- Market the TDM program and transit service
- Advertise the unbundled parking program

- Promote 511.org's ride-matching program

Recommendation: An on-site manager for each company occupying the buildings or a representative of the property management organization should be designated as the Transportation Coordinator and tasked with providing appropriate information to employees and both monitoring and tailoring the TDM program as necessary.

Summary of TDM Reductions

The expected VMT reductions associated with the various TDM measures were estimated based on information published in the California Air Pollution Officers Association (CAPCOA) report *Quantifying Greenhouse Gas Mitigation Measures*, CAPCOA, 2010, the location of the project site, and knowledge of transportation characteristics of the area. Packaged together as a required commute trip reduction program, the TDM strategies listed above are projected to result in a VMT reduction potential of 12.0 percent. The estimated VMT reduction calculations are summarized in Table 11.

Table 11 – Estimated Employee VMT Reduction

TDM Measure	VMT Reduction (%) Project Estimate
Ridesharing Program	8.5
Education, Outreach, and Marketing	4.0
Bicycle Benefits	Supportive
Emergency Ride Home	Supportive
Total Potential VMT Reduction [1]	**12.0**

Notes: VMT = vehicle miles travelled; TDM = transportation demand management

[1] The reductions shown consider the relative effectiveness of reductions when individual TDM strategies are paired with each other, which is not the sum of the individual measures.

Finding – Successful implementation of the TDM measures identified in this report, such as use of a ridesharing program, offering secure bicycle parking, and providing educational materials strategies, have the potential to reduce project-related travel by 12.0 percent.

Alternative Modes

Pedestrian Facilities

Given the nature of the study area and the surrounding industrial land use, it is reasonable to assume that very few project patrons and employees will desire to walk to reach the project site. There may, however, be a desire by employees to walk in the area for recreational purposes during break times or to reach nearby buildings. Upon completion of the project, sidewalks will be provided along Devlin Road between Green Island Road to South Kelly Road. The project also includes the construction of a multi-modal path along Green Island Road which would be available for use by pedestrians.

Finding – Pedestrian facilities serving the project site are adequate and would be further improved upon completion of the sidewalks along Delvin Road and the multi-modal path along Green Island Road.

Bicycle Facilities

Existing bicycle facilities, including Class II bike lanes on Devlin Road between Middleton Way and South Kelly Road together with shared use of minor streets provide adequate access for bicyclists. The project would include bicycle lanes along the Devlin Road extension and a multi-modal path along the north side of Green Island Road. The planned Class I and II bicycle facilities on South Kelly Road and Green Island Road, as well as the Napa Valley Vine Trail along Devlin Road, would improve bicycle connectivity near the project site.

Finding – Bicycle facilities serving the project site are adequate and would be further improved upon completion of the planned bicycle facilities in the study area.

Bicycle Storage

The project site plan does not identify the provision of bicycle parking or storage facilities.

Finding – The adequacy of the bicycle parking facilities at the site are deemed to be inconclusive since the current site plan does not include a sufficient level of detail.

Recommendation – Bicycle parking serving the project site should be designed to comply with City of American Canyon municipal code requirements and to support the TDM Plan for the project.

Transit

Existing stops are not within an acceptable walking distance of the site. Should an employee need to use transit, they could ride a bicycle along Devlin Road to the nearest transit stop at the intersection of Airport Boulevard/Devlin Road.

Finding – The lack of existing transit service within an acceptable walking distance of the project site is typical for such remote locations and is therefore considered acceptable, though employees could use a bicycle to reach nearby transit stops.

Access and Circulation

Site Access

Vehicular access to Phase 1 would be provided via four driveways on Green Island Road and four driveways on the future extension of Devlin Road. Access to Phase 2 is anticipated to be provided via numerous full access driveways with connections to the Devlin Road extension. All driveways and internal roadways would be designed to current City standards to accommodate heavy vehicles and so can be expected to accommodate the access requirements for both emergency and passenger vehicles.

Sight Distance

A substantially clear line of sight should be maintained between the driver of a vehicle waiting at a driveway and the driver of an approaching vehicle. Sight distances along Green Island Road from the project driveways were evaluated based on sight distance criteria contained in the *Highway Design Manual* published by Caltrans. The recommended sight distance for driveway approaches is based on stopping sight distance using the approach travel speed as the basis for determining the recommended sight distance. Based on the posted speed limit of 40 mph, the minimum stopping sight distance required is 300 feet; a review in the field shows that sight distances at the project driveway locations on Green Island Road would be adequate, provided any vegetation or buildings are sited to ensure maintenance of adequate sight lines. The sight lines for driveways on the Devlin Road connection are expected to be adequate based on a review of the site plans.

Finding – Adequate sight distance would be available at each driveway to accommodate all turns leaving the site. To maintain minimum sight distance standards, it is recommended that vegetation along Green Island Road and the Devlin Road extension be trimmed and maintained by the property management firm.

Parking

The *City of American Canyon Municipal Code, Chapter 19.21.030; Vehicle parking requirements*, states that warehousing and storage projects are required to provide one parking space per 1,000 square feet of gross floor area for the first 20,000 square feet of space, plus one parking space per each 2,000 square feet of gross floor area thereafter. Phase 1 of the project includes two buildings totaling 1,069,904 square feet of warehouse space with 858 parking spaces (428 at Building A and 430 at Building B). The site plan for Phase 2 is currently under development and the size and arrangement of the buildings as well as the specific number of parking spaces has not yet been established. Assuming a conservative total project size of 2,400,000 square feet, Phase 2 would be comprised of approximately 1,330,100 square feet of warehouse. Based on these parameters, the project would be required to provide a total of 1,230 parking spaces (555 with Phase 1 and 675 with Phase 2). Phase 1 of the project as proposed would provide 858 parking spaces, which is greater than the City requirement for that portion of the project and represents a 303-parking space surplus. A summary of the City parking requirements and proposed supply is provided in Table 12.

Table 12 – Parking Analysis Summary

Land Use	Units (ksf)	Supply (Parking Spaces)	City Code Requirements	
			Rate	Parking Spaces Required
Warehousing and Storage (Phase 1 – Building A)	601.4	428	1 per 1,000 square feet for the first 20,000 square feet, plus 1 per 2,000 square feet thereafter	311
Warehousing and Storage (Phase 1 – Building B)	468.5	430		244
Warehousing and Storage (Phase 2)	1,330.1	TBD		675
Total	2,400.0	TBD		1,230

Notes: ksf = 1,000 square feet; TBD = To Be Determined;

Finding – Based upon City requirements and a maximum project size of 2.4 million square feet, the project would be required to provide 1,230 parking spaces.

CEQA Checklist

This section details discussion and results of the analysis of issues identified in the CEQA checklist for potential transportation/traffic impacts. The results are contained in Table 13 below and a discussion of each criterion follows.

Table 13 – XVII. TRANSPORTATION/TRAFFIC

Would the Project:	Potentially Significant Impact	Less than Significant Impact with Mitigation	Less than Significant Impact	No Impact
a) Conflict with a program, plan, ordinance, or policy addressing the circulation system, including transit, roadway, bicycle, and pedestrian facilities?			X	
b) Conflict or be inconsistent with CEQA Guidelines § 15064.3, subdivision (b)?			X	
c) Substantially increase hazards due to a geometric design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?			X	
d) Result in inadequate emergency access?			X	

Discussion of Results

a. Would the Project conflict with a program, plan, ordinance, or policy addressing the circulation system, including transit, roadway, bicycle, and pedestrian facilities?

According to the *City of American Canyon General Plan*, numerous objectives, policies, and programs have been established supporting the need for all modes of travel to be accommodated by the transportation system. This is demonstrated through the following General Plan Guiding Policies.

- **Policy 1.6 Achieve and maintain a Multimodal LOS D or better for roadways and intersections during peak hours where possible and as long as possible.** The locations that may not achieve or maintain LOS D are as follows and will be exempt from the LOS D policy: State Route 29 through the City, American Canyon Road from SR 29 to Flosden Road-Newell Drive, and Flosden Road south of American Canyon Road.
- **Policy 1.9 Use of existing facilities.** Make efficient use of existing transportation facilities and improve these facilities as necessary in accordance with the Circulation Map.
- **Policy 1.11 Reduce Vehicle Miles Traveled.** Through layout of land uses, improved alternate modes, and provision of more direct routes, strive to reduce the total vehicle miles traveled by City residents.
- **Policy 2.1 Promote walking and bicycling.** Promote walking and bike riding for transportation,
- recreation, and improvement of public and environmental health.
- **Policy 3.1 Promote safe, efficient, and convenient public transportation.** Promote the use of public transportation for daily trips, including to schools and workplaces, as well as other purposes.

Roadway Facilities

The proposed project would not cause any study intersections to which it applies to operate below the City's standard of LOS D. The project's roadway impacts would therefore be less-than-significant, and no mitigation measures are required. It should be noted that while SR 29/South Kelly Road would operate at LOS F under Future Conditions without or with the project, this intersection is exempt from the City's LOS standard and Caltrans no longer has an operational standard.

Pedestrian Facilities

The proposed project would provide pedestrian connectivity infrastructure on-site as well as sidewalks along Devlin Road. With these improvements, pedestrian impacts would be reduced to less-than-significant.

Bicycle Facilities

Shared use of minor streets combined with the Class II facility on Devlin Road provides adequate access for bicyclists. Therefore, bicycle impacts would be less-than-significant.

Transit Facilities

The Valley Intercity Neighborhood Express (VINE) Transit provides fixed route bus service in American Canyon. VINE does not currently serve any bus stops within an acceptable walking distance of the site. Should an employee wish to use transit, they could ride a bicycle along Devlin Road to the nearest transit stop north of the project at Airport Boulevard. The lack of transit service within an acceptable walking distance of the project is typical within this area and would therefore be considered a less-than-significant impact.

b. Would the Project conflict or be inconsistent with CEQA Guidelines § 15064.3, subdivision (b)?

CEQA Guidelines §15064.3, Subdivision (b) indicates that land use projects would have a significant impact if the project resulted in vehicle miles traveled (VMT) exceeding an applicable threshold of significance. It further notes that if existing models or methods are not available to estimate the VMT for the project being considered, a lead agency may analyze the project's VMT qualitatively. The City of American Canyon currently has no thresholds of significance related to VMT, and as of the date of the analysis, a regional travel demand model for Napa County is under development but not yet available for VMT analysis. The project was assessed quantitatively using the Statewide Travel Demand Model and determined to have a less-than-significant VMT impact.

c. Would the Project substantially increase hazards due to a geometric design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?

As part of the project, a new segment of Devlin Road would be constructed resulting in a continuous section of roadway running between South Kelly Road and Green Island Road. The project itself as well as the new segment of roadway would be designed and constructed to meet currently applicable codes and requirements, so would not be expected to result in any increased hazards. Project driveways would be expected to have adequate sight lines. The project is therefore expected to have a less-than-significant impact regarding geometric design features or incompatible uses.

d. Would the Project result in inadequate emergency access?

The project site would have adequate emergency access and would improve emergency access and response times to the area near Devlin Road with the provision of a new street connection; therefore, the project would result in a less-than-significant and in fact beneficial impact related to emergency access.

Conclusions and Recommendations

Conclusions

- The proposed project is expected to generate an average of 3,888 passenger-car equivalent trips per day, including 240 trips during the weekday a.m. peak hour and 264 during the p.m. peak hour.
- Under Existing Conditions all study intersections operate acceptably, and they are expected to continue doing so upon the addition of project-related traffic.
- Under anticipated Future volumes the unsignalized study intersections are expected to operate acceptably without or with the addition of project-related traffic. SR 29/South Kelly Road would operate at LOS F either without or with project traffic, which was considered acceptable since SR 29 is exempt from the City's LOS policy.
- The proposed project would have a less-than-significant transportation impact on vehicle miles traveled. Successful operation of the recommended Transportation Demand Management Plan is expected to further lower project-related VMT.
- Pedestrian access would be adequate upon completion of the sidewalks and trail that are part of the proposed project.
- The shared use of minor streets along with the planned facilities outlined in the Napa Countywide Bicycle Plan would provide adequate access for bicyclists, though the project site plan does not identify the provision of bicycle parking.
- The lack of existing transit service within an acceptable walking distance of the project site is typical for this location and is therefore considered acceptable, though employees could use a bicycle to reach nearby transit stops.
- The project's driveways and internal roadways should be designed to current City standards and are therefore expected to accommodate the access requirements for both emergency and passenger vehicles.
- Although sight lines at the project driveways are or would be adequate for the approach speeds, it is recommended that vegetation be trimmed and maintained along Green Island Road and the Devlin Road extension to maintain the minimum sight distance requirements.
- Based upon City requirements, the project is required to provide 1,230 parking spaces.

Recommendations

- As required by the City in their Traffic Impact Fee Program, the project should pay a fee toward the cost of the planned future improvements to SR 29.
- Landscaping, buildings, and signage along the project frontage should be sited to ensure that adequate sight lines are maintained.
- The project should incorporate TDM measures such as a ridesharing program, offering secure bicycle parking, and educational materials to further reduce their carbon footprint.
- Secure bicycle storage should be provided, if not already planned as part of on-site amenities.

EXECUTIVE SUMMARY

Giovannoni Logistics Center ("Project") in the City of American Canyon in Napa County, California, is a proposed light industrial project. The Project is bounded by the Napa Logistics Park and Devlin Road to the north, Green Island Road and warehouses to the south, Green Island Road Business Park to the west, and Union Pacific Railroad/Napa Branch Line to the east. The Project is broken up into two construction phases. Phase 1 is the eastern portion of the project including two warehouses with roughly 1.1 million square feet of warehouse space. Phase 2 is the western portion of the project with conceptually up to 1.3 million square feet of similar uses.

This Water Supply Assessment (WSA) presents the proposed potable and recycled water use for the Project, and assesses the potential impact to citywide supply and demand projections through the year 2040 for the City of American Canyon. The Project would be served by water provided by the City of American Canyon. Phase 1 is estimated to use up to 10.8 acre-feet per year (afy) of potable water to serve the two warehouses at the site, and up to 37.1 afy of recycled water, predominantly for landscape irrigation. Phase 2 is estimated to use up to 13.1 afy of potable water for warehouses and up to 45.0 afy of recycled water for landscape irrigation.

The Project will use less potable water over the long-term than was assumed in the demand analysis in the City's Urban Water Management Plan (UWMP) for the project site (133.3 afy less). In addition, compliance with the City's Zero Water Footprint policy would offset the Project's potable demand through off-site implementation of project-funded water conservation measures of up to 23.9 afy. The citywide supply/demand analysis in this WSA anticipates sufficient supply in all normal years, but shortfalls in water supply during dry-year scenarios in 2035 and 2040, consistent with the analysis in the 2015 UWMP. State Water Project carryover water is anticipated to be available in amounts great enough to accommodate these deficiencies. In addition, the City may choose to make use of other options available, including Advanced Table A Water, drought demand restrictions, or water purchases on the open market. As such, adequate supply is projected to be available under all planning scenarios.

The City produces recycled water to meet demand and, along with recycled water supplied by the Napa Sanitation District, has sufficient long-term supply capacity to meet projected demand both at the project site and throughout the City's service area.

1 INTRODUCTION

This report analyzes the projected water supply and demand for the Giovannoni Logistics Center (Project) in the City of American Canyon in Napa County, California. The Water Supply Assessment (WSA) is intended to support environmental planning documentation for the Project, which includes approximately 2.4 million square feet of warehouse space.

1.1 Regulatory Background

Section 10910 of the California Water Code (as revised by Senate Bill 610, or SB610) requires: "The city or county, at the time that it determines whether an environmental impact report, a negative declaration, or a mitigated negative declaration is required for any project subject to the California Environmental Quality Act, pursuant to Section 21080.1 of the Public Resources Code, "…[to] identify a water system…that may supply water for the project," and to prepare a WSA to address the increased water use over existing conditions. The WSA is intended to:

1. Identify the water system or systems that would (or may) supply water to the project;
2. Compare project water demands with those projections included in the most-recently adopted Urban Water Management Plan or Plans for those service providers; and
3. Assess whether the public water system's total projected water availability for the entire system(s) during normal, single dry, and multiple dry years over a 20-year period will meet the projected water demand associated with the proposed project, in addition to the public water system's existing and planned future uses (including agricultural and manufacturing uses).

Within this assessment, California Water Code Section 10910(4)(d) requires a discussion of existing water supply entitlements, water rights, or water service contracts relevant to the public water system(s). Also, Section 10910 (2)(f) requires that "If a water supply for a proposed project includes groundwater, the following additional information shall be included in the water supply assessment: (1) a review of any information contained in the urban water management plan relevant to the identified water supply for the proposed project (2) a description of any groundwater basin or basins from which the proposed project will be supplied."

The proposed Project is a logistics warehouse complex on approximately 208 acres with 2.4 million square feet of warehouse space. Section 10912(a) of the California Water Code outlines the types of projects requiring a Water Supply Assessment, including:

- "A proposed industrial, manufacturing, or processing plant or industrial park planned to house more than 1,000 persons, occupying more than 40 acres of land, or having more than 650,000 square feet of floor area."

As such, the Project requires a WSA. See Section 3.1 for a discussion of estimated water demand for the Project.

Water supply for the proposed project would be served by the City of American Canyon ("City"). Water sources available to the City are discussed in Section 2. The City prepared a 2015 Urban Water Management (UWMP) (Kennedy Jenks, 2016) that projected water supply and demand within the service district through 2040. While the Project was not explicitly named in the 2015 UWMP, the UWMP did generally account for projected increases in demand associated with expected development in the city limits of American Canyon, including the parcel for the Project. Section 3.2 discusses the differences in potable and recycled water demand of the proposed project area compared to the assumed demand. Section 4 compares the system-wide supply and demand for the City to assess whether there is sufficient supply to support existing water uses, the Project, and other planned future uses through 2040.

1.2 Project Location

The Project is located in the northern portion of the City of American Canyon in Napa County, California. The proposed development is bounded by the Napa Logistics Park and Devlin Road to the north, Green Island Road and warehouses to the south, Green Island Road Business Park to the west, and Union Pacific Railroad/Napa Branch Line to the east. The Project is broken up into two construction phases. Phase 1 is the eastern portion of the project including two warehouses, roughly 1.1 million square feet of warehouse floor space. Phase 2 is the western portion of the project with conceptually up to 1.3 million square feet of warehouse space.

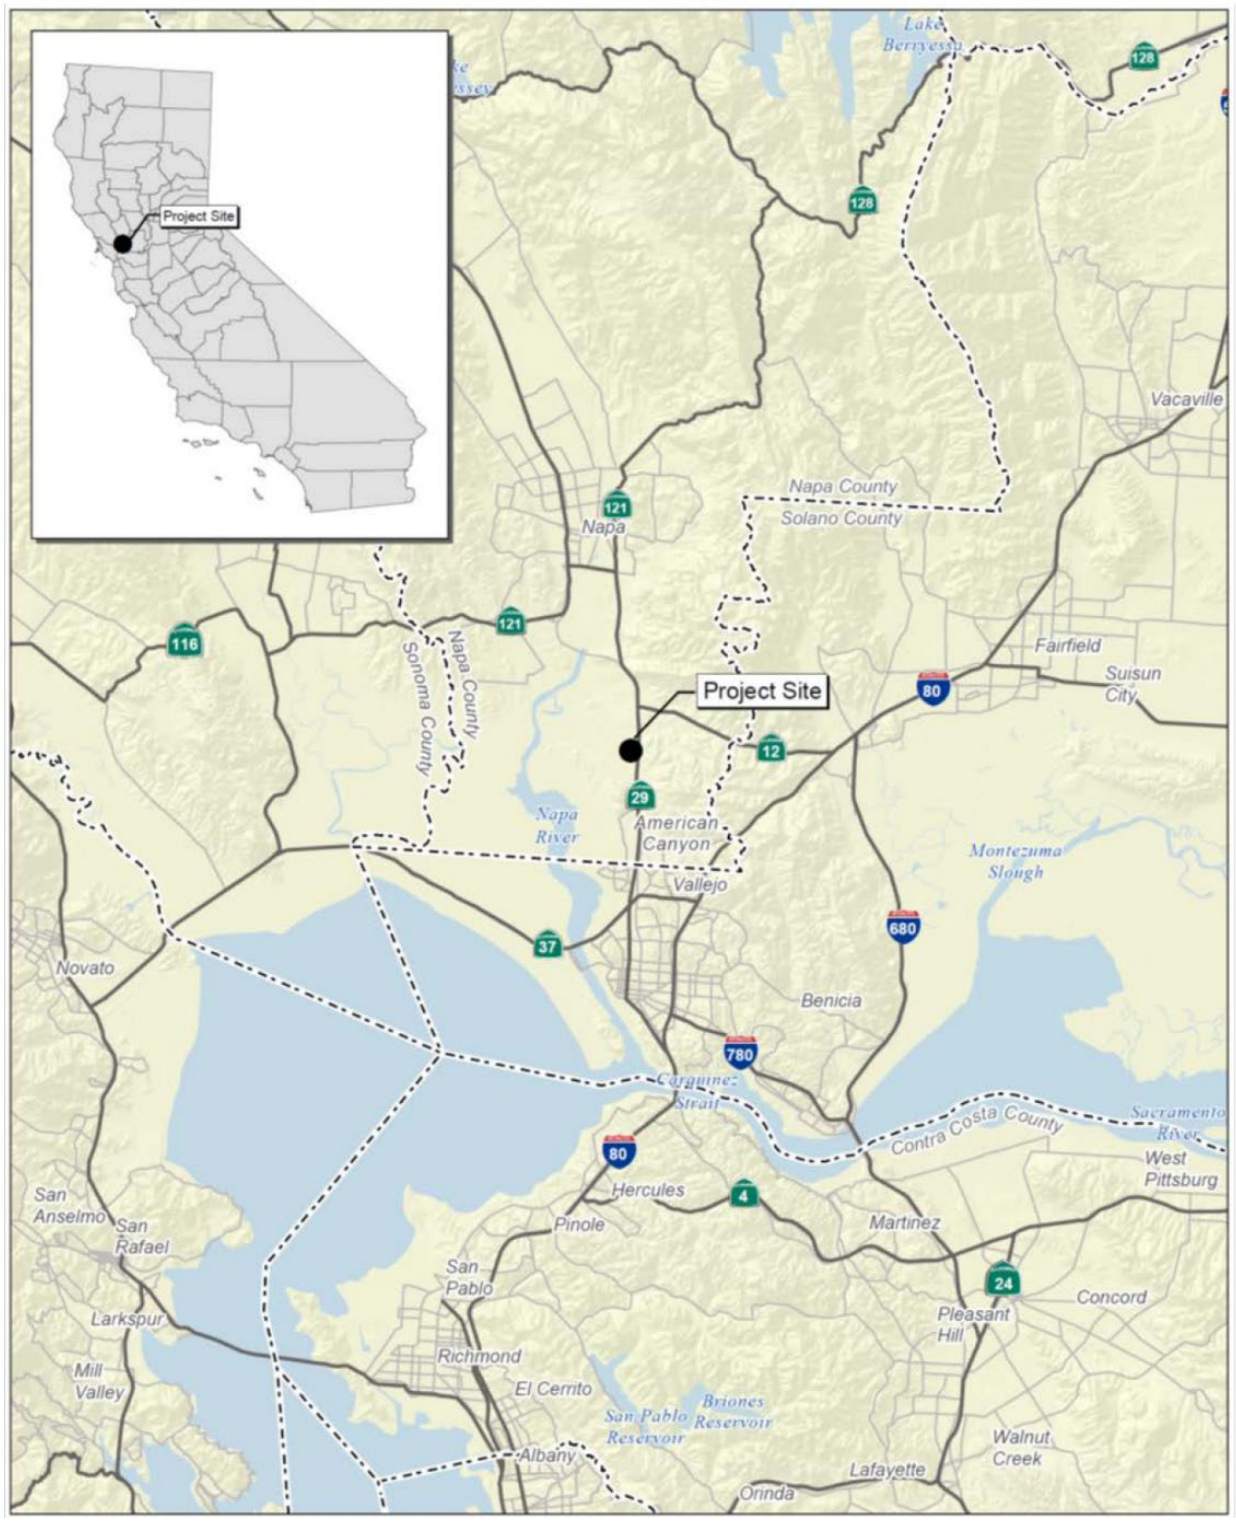

Figure 1-1 Project Location

1.3 Existing Conditions

The project site is currently undeveloped parcels composed generally of mix grasses and several seasonal wetlands. Most of the seasonal wetlands on the proposed project site are located on the northern edges of the parcel and will be left as a wetland/mitigation preserve outside the development footprint of the project.

1.4 Proposed Project

The proposed project entails developing 208-acres for light industrial uses constructed in two phases. Phase 1 is the 94.7-acre area east of Devlin Road extension, including two warehouses, totaling roughly 1.1 million square feet, associated impervious surfaces, stormwater facilities, and wetland preservation areas. Phase 2 is the 113.1-acre area west of Devlin Road, and would conceptually include up to 1.3 million square feet of warehouse space and associated infrastructure. In total the Project would develop 161 acres, leaving 47 acres as open space, including the northern portion of the project site adjacent to No Name Creek. **Figure 1-2** shows the proposed project layout, as described in the Project's Stormwater Control Plan (Balance, 2021)[1].

Potable water supply for the Project will be served by the City of American Canyon, and landscape irrigation will be supplied by recycled water, also from the City, via water infrastructure installed within Devlin Road extension. Laterals would extend from Devlin Road water lines to project warehouses (**Figure 1-3**).

[1] Note that only Phase I is shown in the figure. Phase II is being evaluated at a programmatic level, and thus specific site plans for this portion of the site have not yet been completed. It is expected that the site would include warehouses, similar to Phase I, with up to 1.3 million square feet of floor space.

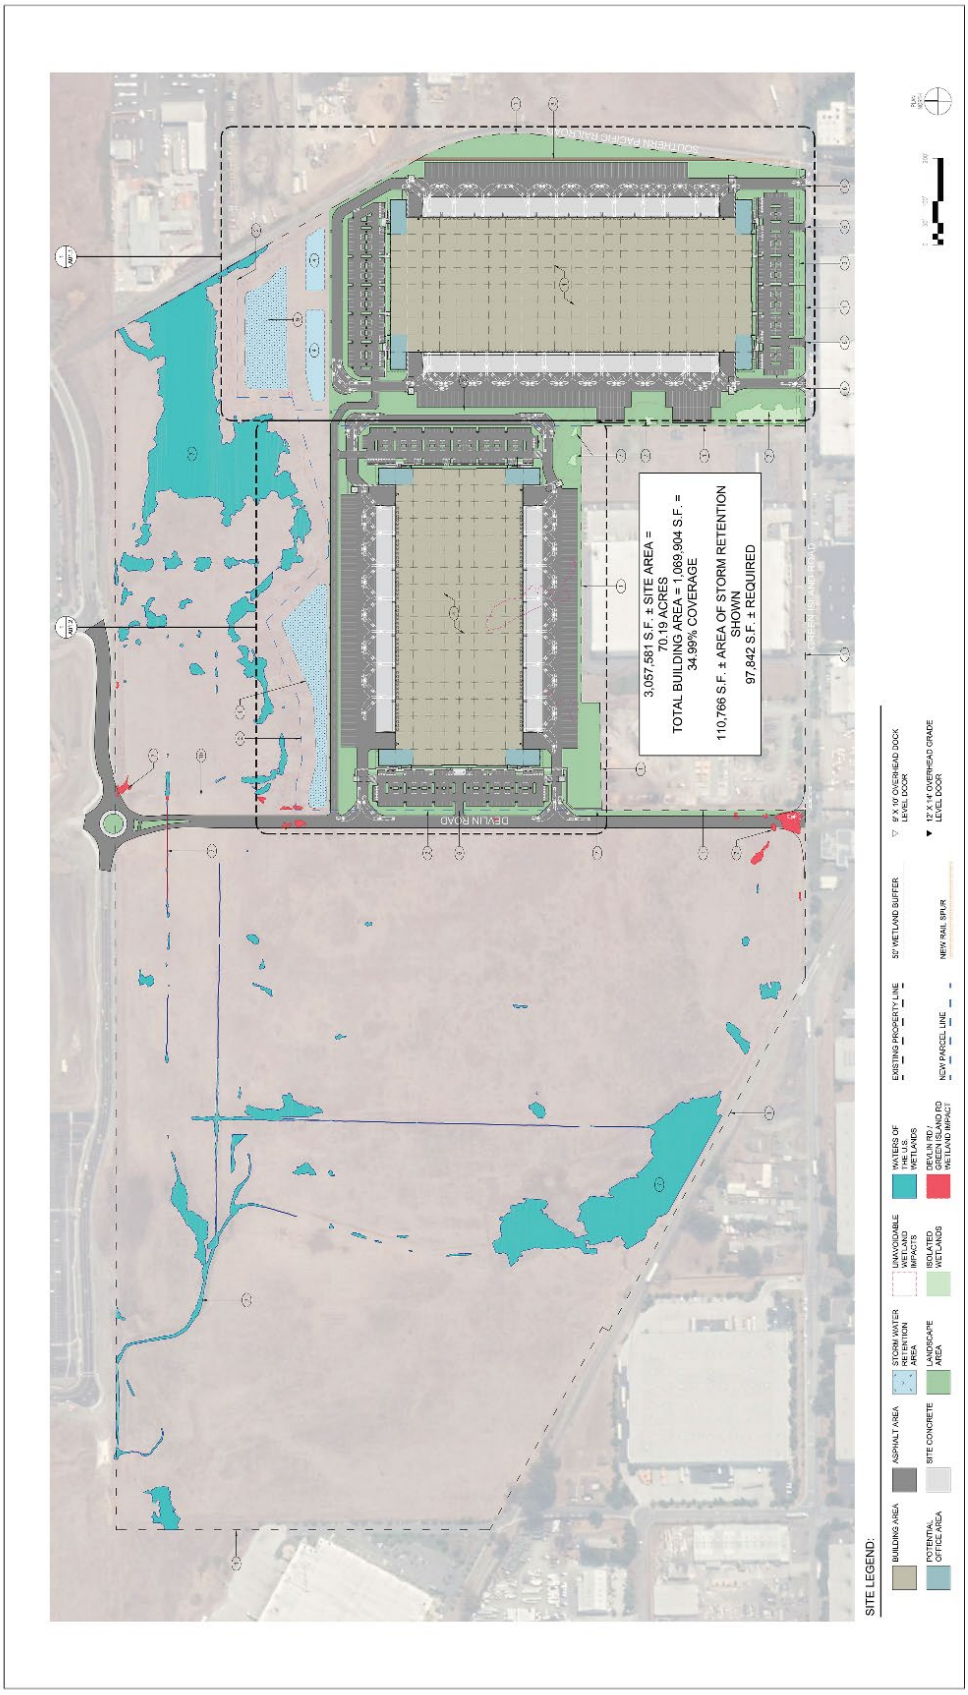

Figure 1-2 Proposed Project

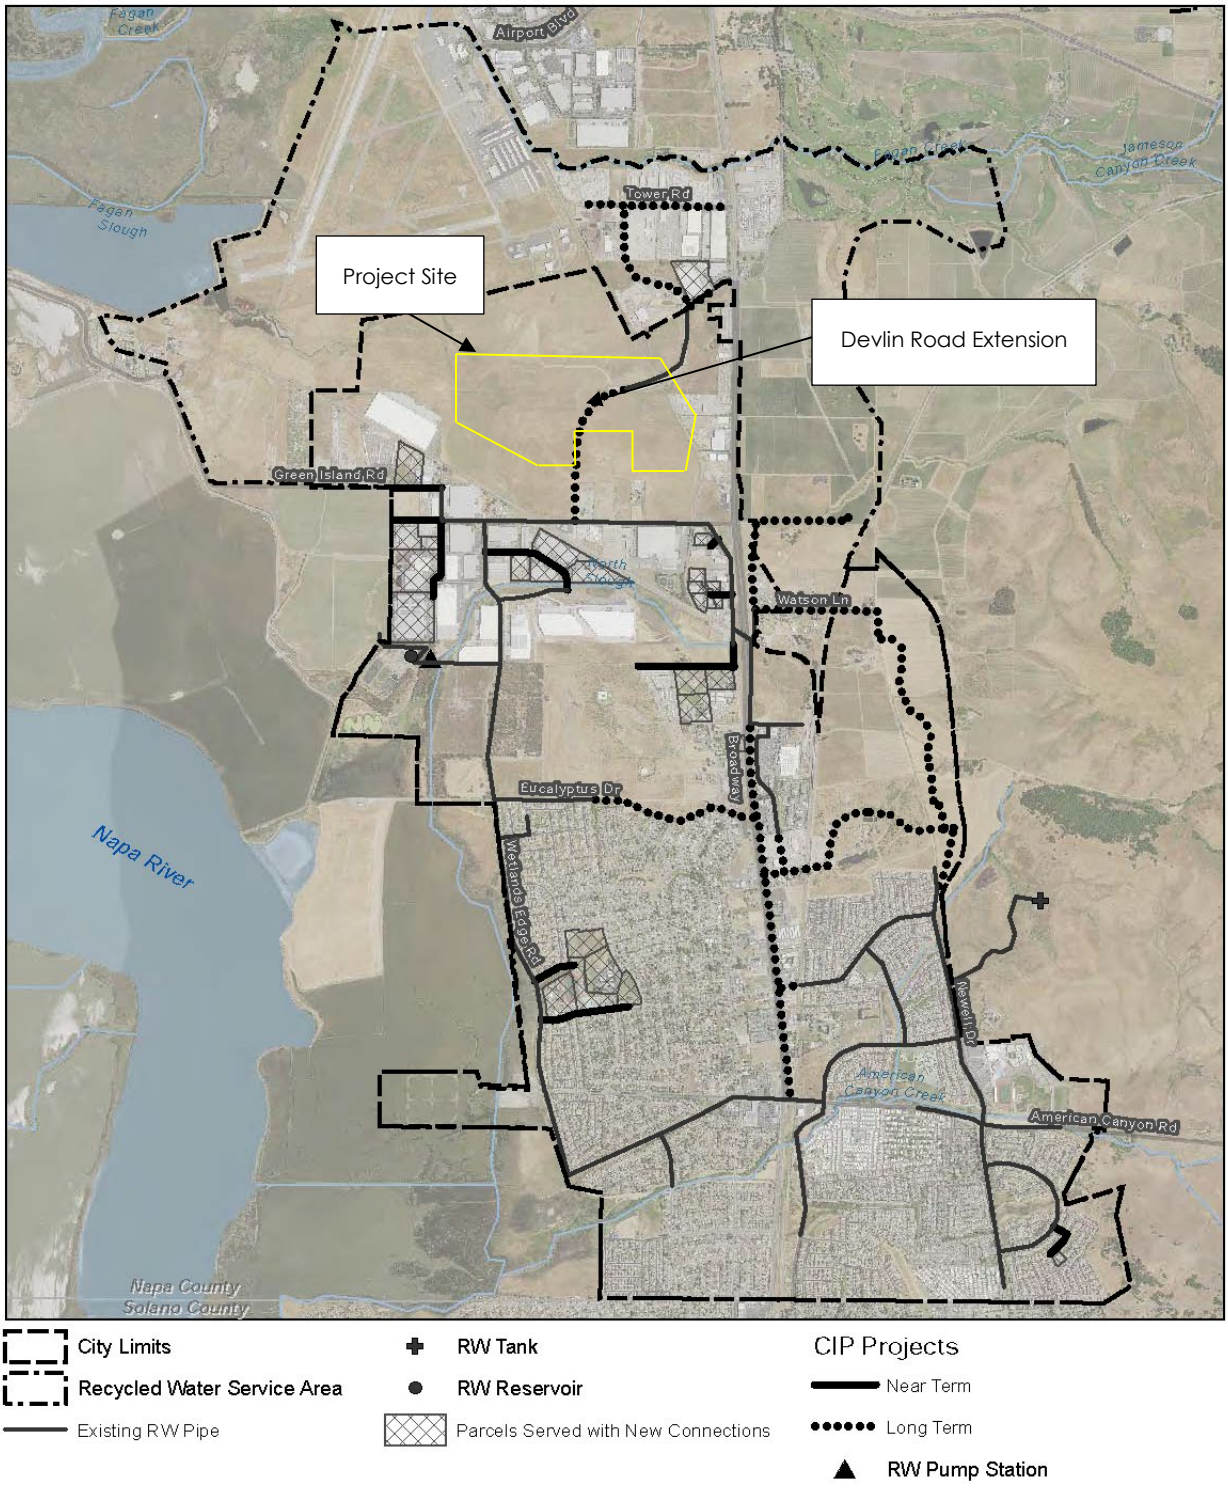

Figure 1-3 **Existing and Planned Recycled Water System for the City of American Canyon, California**. As reported in the City of American Canyon Recycled Water Master Plan, 2016.

2 WATER SUPPLY

American Canyon obtains its water supply from a variety of sources, all of which (except for recycled water) are imported from outside of the City. All of the City's imported water comes through the North Bay Aqueduct (NBA) system. The following sections summarize the various sources of water for American Canyon (see also **Table 1**). These descriptions were summarized from American Canyon 2015 Urban Water Management Plan (2015 UWMP; Kennedy Jenks, 2016).

2.1 State Water Project

A significant portion of the City's supply is obtained through various indirect contracts for water from the State Water Project (SWP). The Napa Flood Control and Water Conservation District (District) is the State Water Contractor with the California Department of Water Resources (DWR), and the City receives its water through subcontracts with the District.

2.1.1 Table A Allocation

In January 1967, the American Canyon County Water Agency [2] entered into an agreement with the District for water supply from the North Bay Aqueduct. In 2010, the agreement allowed for the delivery of up to 5,200 acre-feet of water per year[3]. This contract runs through 2035 with provisions for extension. The actual amount of SWP water available to the City under the "Table A" allocation process (the method used by DWR to allocate water in the SWP system) varies from year to year due to hydrologic conditions, water demands of other contractors, SWP facility capacity, and environmental/regulatory requirements. Deliveries have varied between 5% (in 2014) and 100% (last occurring in 2017) of the contracted amount.

2.1.2 Article 21

Article 21 is a long-term water supply contract with DWR. This contract varies each year depending on excess water in the Delta, excess water not allocated for other purposes

[2] A predecessor agency to the City of American Canyon, which wasn't incorporated until 1992.
[3] 500 AF of this water was obtained through a purchase of water, by the Napa Sanitation District, from Kern County Water Agency in 2000.

or water deliveries, and the capacity within the City's own system to store the Article 21 purchased water.

Table 1 Current Sources of water supply for American Canyon

Source	Contracted Volume/Capacity (afy)
State Water Project ('Table A' allotment)[1]	5,200
Vallejo Permit (Raw) Water[2]	500
Vallejo Treated Water	
(2011-2015)	2,074
(2016-2021)	2,640
(2021-onward)	3,206
Vallejo Emergency (Raw) Water [3]	500
Groundwater [4]	0
American Canyon Recycled Water [5]	1,271
Napa Sanitation District Recycled Water	591

Notes:

[1] *Includes allottment for American Canyon and additional supply from Kern County Water Agency.*

[2] *Non-Table A water.*

[3] *Available only in dry years.*

[4] *No groundwater is used for City-wide supply*

[5] *As reported in 2015 UWMP . Maximum capacity of City's recycled water treatment system by 2035*

2.2 Water from the City of Vallejo

In 1996, the City entered into an agreement with the City of Vallejo to allow the purchase of additional water supply. Vallejo receives its water from a variety of sources, including SWP water and an appropriative water right. Under the Vallejo Agreement, a specific source is identified for Permit Water supply (see Section 2.2.1, below), but not for Treated or Emergency Water (Sections 2.2.2 and 2.2.3).

2.2.1 Vallejo Permit Water (Raw)

Vallejo holds an appropriative right for Sacramento Bay-Delta water from the State Water Resources Control Board that pre-dates the construction of the SWP. The City has an agreement with Vallejo for delivery of up to 500 acre-feet of water under this permit. This source of water is more reliable than the City's Table A supply, but the Vallejo Agreement still allows for reductions. Addendum 2 to the 1996 Vallejo Agreement states that "In the event the State Water Resources Control Board, or any other agency, restricts Vallejo's

diversion of water [under the appropriative pre-SWP contract] for any reason whatsoever, American Canyon's diversions will be reduced in the same proportion". As such, the City may not receive its full allotment during dry years[4].

2.2.2 Vallejo Treated Water (Potable)

In 1996, the City entered into an agreement with Vallejo to purchase up to 629 acre-feet of potable treated water supply. This agreement included the option for additional (cumulative) purchases in 5-year increments through 2021. Ultimately, this results in a total of 3,206 acre-feet of treated water available for purchase each year by the City from Vallejo for 2021-2040.

A specific source for Treated Water is not identified in the Vallejo Agreement; thus, the ultimate source of this water is a blend of all of Vallejo's water sources. Under certain conditions, the maximum delivery of this supply may be "reduced in the same proportions as any reduction to Vallejo customers inside the Vallejo City limits"[5].

2.2.3 Vallejo Emergency Water (Raw)

When the City's Table A water allotment is curtailed, the City has the option to purchase up to 500 acre-feet of emergency raw water supply from Vallejo, under an agreement amended in 1996. The 2015 UWMP assumes that this water would be available under a dry-year and multiple-dry-year scenarios, but not during a normal year.

2.3 Groundwater

The City of American Canyon does not currently rely on groundwater as a source of water, though the 2015 UWMP states that the City remains open to the possibility and will consider potential supply opportunities as they present themselves. The Project will not be using groundwater sources and therefore detailed information on groundwater outlined in Section 10910(f) of the California Water Code is not required for this Water Supply Assessment.

[4] Vallejo Permit Water delivery was curtailed in both 2014 and 2015, for example. However, the City received its full allotment before the curtailment took effect.

[5] Vallejo Water Service Agreement, May 1, 1996 (Appendix E.4 in the 2005 American Canyon UWMP).

2.4 Other Sources of Potable Supply

2.4.1 Dry-Year Water Bank

In 2009, the City (along with other SWP contractors) entered into an agreement with DWR to obtain emergency supplies if rice farmers in the Sacramento Valley are willing to make their supplies available. The year-to-year availability of this supply is not known, and thus supplies are not factored into long-term planning in the 2015 UWMP.

2.4.2 Turn-back Water Pool Program

DWR has a program for interested SWP contractors called the Turn-back Water Pool Program. SWP contractors may choose to sell Table A water or purchase turn-back pool water that is available through the program. Water from this pool program was not included in the reliability assessment in the 2015 UWMP because the program operates on an as-available basis and long-term availability is not reliable. The amount of pool water available to the City is not a significant amount. For example, during 2010 the City purchased 17 acre-feet, and in 2012 it purchased 64 acre-feet. However, between 2015-2020 the City did not purchase any water from the Turn-back Pool Program.

2.4.3 Napa Treated Water

The City has an agreement with the City of Napa for the purchase of treated (potable) water under emergency conditions, or when the NBA system is offline for maintenance or other reasons. This water source is not a water supply and is not included in the reliability assessment in the 2015 UWMP since it is only available during emergencies. Napa treated water, however, does provide operational flexibility (such as providing water to customers even when the City's water treatment plant is off-line for an extended period of time). During 2010, the City purchased 306 acre-feet of treated water when the plant was off-line for maintenance-related issues. Under this informal arrangement, the Napa treated water purchase counts against the City's SWP Table A allotment and is not an additional supply (and is not included in **Table 1**).

2.4.4 Dry Year Transfer Program

During dry years, varying amounts of additional water may be made available to SWP contractors through DWR's Dry Year Transfer Program, which allows for transfers through a combination of crop idling, groundwater substitution and changes in reservoir operation. For example, in 2015 the City of American Canyon purchased 92 af of additional supply (for that year) through this program. While this option is available to the

City on a per-year authorization, the long-term reliability of this supply is not known and included only as potential supplementary supply for the analysis in this WSA.

2.4.5 Yuba Accord

In 2008, DWR adapted the Lower Yuba River Accord, an agreement to settle issues related to in-stream flows in the Yuba River and fisheries habitat. As part of that agreement, DWR is able to purchase water from the Yuba River Water Agency to, in part, offer to participating SWP contractors as a transfer during dry years. The Napa County FCWCD has authorized the execution of Yuba Accord Dry-year Water Purchase Agreement, and the City has the option to purchase water through this agreement in dry years, though at a cost that is considerably higher than under normal conditions. In 2015, the City authorized the purchase of 124 af through this program in response to cover projected water supply shortfalls during the drought. While this option is available to the City in drought conditions, the availability and reliability of such water past 2020 is unknown[6], and therefore has not been included as long-term reliable supply for the analysis in this WSA.

2.5 Recycled Water

2.5.1 American Canyon Recycled Water

In 2010, the City completed the first phase of its Recycled Water Distribution System Project, which included a one-million-gallon reservoir, distribution piping, and associated improvements at the City's water treatment plant. Initially, 13 users were connected to the system and 73 acre-feet of water was delivered in 2010. Ultimately, the Recycled Water Master Plan in 2016 projected over 1,200 acre-feet of water demand at build-out in 2035 for landscaping and agricultural irrigation. However, utilization of this supply is dependent on connection of additional users and completion of additional distribution pipe segments. Currently, the City produces recycled water to meet demand on an as-needed basis.

The City is currently taking steps to increase capacity of their system to meet this demand in the future. The analysis in this WSA uses 1,271afy as the full system capacity by 2035, as reported in the 2015 UWMP.

[6] The original term of the NCFCWCD agreement was through the end of 2015, but an amendment in 2014 authorized an extension until the end of 2020.

2.5.2 Napa Sanitation District Recycled Water

In addition to the City's recycled water supply, Napa Sanitation District (NSD) has an existing recycled water supply pipe that extends to northern portions of the Airport Industrial Area (north of Fagan Creek). In 2015, NSD provided 210 acre-feet of recycled water to the City's users. The 2015 UWMP projected that NSD will provide up to 391 acre-feet of recycled water in 2020, up to 491 acre-feet in 2025, and 591 acre-feet in 2030 and onwards.

3 WATER DEMAND

The following section summarizes the anticipated potable- and recycled-water demand for the proposed Project, and compares the anticipated demand of the Project to demand assumptions in the 2015 UWMP for those parcels. Section 3.3 discusses system-wide demand for the City.

3.1 Project Demand

As described in Section 1.4, the proposed Project contains two warehouse buildings for Phase I, and additional warehouse buildings as part of Phase II. In addition, the Project will include associated landscaping areas that will require seasonal irrigation. The wetland preservation area is not expected to require supplemental water after the establishment of mitigation wetlands.

3.1.1 Potable Water

Potable water demand for the Project was estimated by CBG Engineers (see Appendix A) based on demand factors contained in the 2016 City of American Canyon Potable Water Master plan, and is summarized in **Table 2**. These estimates were calculated using an average day demand of 0.015 gpd/sf which is the average water use across all the industrial sector and believed to be an overly high estimate of water use for this project[7]. Therefore, revised potable water use projections for the Project were calculated using averages from other similar commercial warehouse projects with more in-depth water demand estimates and/or metered water usage, as further discussed below.

The Napa Airport Corporate Center (NACC) is an industrial warehouse development just North of the Project in the City of American Canyon. Multiple industrial warehouse buildings are planned in this development (buildings B, D, E, G, and H). Details of the water demand estimates are reported in the NACC Water Supply Assessment report (Balance Hydrologics, 2015), with an estimated average day demand of 0.006 gpd/sf[8] . Similarly, Suisun Logistics Center is a planned industrial warehouse project in Fairfield, California also owned and operated by Buzz Oates. That project used water meter data from similar Buzz Oates developments in Fairfield to project anticipated potable water

[7] Warehouse space typically uses less water than most other industrial uses that often include industrial process water in addition to the water needed to supply employees (sinks, bathrooms, etc.).

[8] Building A of the NACC project is considered mix-used and was left out of the average day demand calculation for the industrial warehouse water demand estimates.

demand. Using actual water use from four industrial developments, Suisun Logistics Center average day demand is estimated at 0.01 gpd/sf (Appendix B). In order to provide a more realistic estimate of potable water demand for the Giovannoni Project, we averaged various demand rates described above (CBG, NACC, and Suisun Logistics Center), resulting in an average day demand of 0.009 gpd/sf. This revised average day demand was used to calculate a revised potable water use for the Project and is summarized in Table 2. We estimate the total potable water demand of the project at build-out to be 23.9 afy (15.9 afy less than the usage originally estimated by CBG Engineers).

For the purposes of this WSA, all indoor water demand is assumed to be from potable water. The applicant has not indicated that recycled water would be used for non-potable indoor uses, though that would remain an option to further reduce potable water demand at the site, should the applicant choose[9]. **Table 2** shows the estimated potable water demand for each building of the Project.

[9] The applicant is required to offset potable demand through implementation of the City's Zero Water Footprint policy (see Chapter 5). Use of recycled water for non-potable indoor uses would reduce the amount of the offset needed. However, because the applicant has not indicated this option, this WSA assumes all indoor water use will be from potable supply in order to provide a conservatively high estimate of potable water use.

Table 2 Estimated water demand for the Giovannoni Logistics Center Project, American Canyon, California

Project feature	Building floor area (sq. ft.)	Potable water use[1] (afy)	Revised potable water (afy)	Recycled water use[3] (afy)	Total water use (afy)
Building A - Phase 1	601,383	10.1	6.1	20.8	30.9
Building B - Phase 1	468,521	7.9	4.7	16.2	24.1
Phase 2	1,300,000	21.8	13.1	45.0	66.9
Total	**2,369,904**	**39.8**	**23.9**	**82.1**	**121.9**

Notes:

[1] cbg project estimate based on average day demand of 0.015 gpd/sf from American Canyon Potable Water Master Plan. See Appendix A for details.

[2] Revised potable water use estimates based on average day demand of 0.009 gpd/sf. This is an average generated from three commerical water demand estimates.

[3] Recycled water will be used for all landscape irrigation. Recycled water should be available to the project. Recycled demand estimated using demand factors from Table 3.13 in the 2010 UWMP.

3.1.2 Recycled Water

The Project is proposing to use recycled water for all irrigation needs. Estimated recycled water use within the project is summarized in **Table 2**. The current project plans do not have estimates for the area of irrigated landscaping. We approximated Project irrigation water demand by applying the average ratio of 0.604 between irrigated area and building footprint from the neighboring NACC project (Balance Hydrologics, 2015), with a demand factor of 2.5 acre-feet/acre (from Table 3.13 in the 2010 UWMP). These irrigation demand estimates may be high if the Project plans to landscape with xeric or native plant species that have lower-than-typical irrigation needs.

The recycled water usage estimates in **Table 2** are intended to be used for environmental planning documentation. Actual use per building may vary based on final site plans, but total use is expected to be consistent with (or less than) these assumptions. As stated above, all non-potable indoor water use is anticipated to be served by potable supply, though the option remains open to serve with recycled water, should the applicant choose.

3.2 Project Demand Comparison to UWMP

The following sections compare the current estimates of water demand for the Project to those assumed for that parcel in the 2015 UWMP.

3.2.1 POTABLE WATER

In order to project future system-wide water demand for the 2015 UWMP, the standard demand factors from the 2010 UWMP were used along with a variety of growth-rate estimates for various land-use sectors. For the commercial/industrial sector, the City analyzed the acreage of vacant land zoned for those uses, and applied a water use factor of 675 gallons/day/acre (gpd/ac) to each parcel. The project's demand has been incorporated into long-term projections under an assumption of a build-out use of 675 gpd/ac (0.76 afy per acre).

Table 3 compares the estimated project demand with the assumptions for the parcel included in the 2015 UWMP. Due to relatively low water-use of warehouse space compared to industrial-sector averages, the incorporation of recycled water for irrigation purposes, and the designation of a portion of the site for wetland preservation that will not require supplemental water supply, the Project is expected to use 133.3 afy less water than expected under the 2015 UWMP growth scenario. Implementation of the City's Zero Water Footprint Policy (see Chapter 5) would result in an additional 23.9-acre-foot reduction in potable water demand relative to the UWMP system-wide demand analysis.

Table 3 Estimated water demand compared to assumptions within the 2015 American Canyon UWMP

	Potable Water				*Recycled Water*	
	UWMP[1]	**Project[2]**	**Difference**	**ZWF offset[3]**	**UWMP[4]**	**Project[5]**
	(afy)	(afy)	(afy)	(afy)	(afy)	(afy)
Phase 1	71.6	10.8	-60.9	-10.8	...	37.1
Phase 2	85.6	13.1	-72.5	-13.1	...	45.0
Total	**157.2**	**23.9**	**-133.3**	**-23.9**		**82.1**

Notes:

[1] Commerical demand factors, 2010 UWMP, Table 3.13.

[2] From Table 2.

[3] Required project compliance with the City's Zero Water Footprint policy. The Project will offset potable water use through implentation of various items from the City's "toolbox".

[4] UWMP did not project irrigation demand on a parcel-by-parcel basis. Because Project irrigation will be supplied by recycled water, comparison against projections in the UWMP is not necessary.

[5] Irrigated landcape; from Table 2.

3.2.2 Recycled Water

The American Canyon UWMP assumes irrigation use to be 2.5 acre-feet of water per acre of landscaping, but (unlike for potable demand) did not project recycled water demand associated with particular parcels anticipated for development. Because recycled water use offsets demand for potable (or raw imported) water and it is in the City's best interest to maximize use of recycled water, the Project's recycled water demand is assessed relative to the recycled-water demand goals outlined in the UWMP.

The 2016 Recycled Water Master Plan showed a delivery of 248 acre-feet for an existing 21 users between August 2013 and July 2014. In 2019, 282 acre-feet[10] of recycled water was delivered to customers which is still below the projected 391 acre-feet of recycled water in 2020. This Project would add an estimated 82.1afy of recycled water demand (see **Table 3**, above).

3.3 System-wide Demand

3.3.1 Recent Actual System Demand

The 2015 UWMP provides a comprehensive assessment of anticipated future water demand that included projections for both potable[11] and recycled water for 2015-2040. However, actual water usage between 2015 and 2020 differed from what was projected in the UWMP, suggesting that demand patterns for 2015-2040 may be different as well.

Table 4 shows the actual water usage within the City's distribution area since the 2015 UWMP was completed, as well as the interpolated yearly demand based on the projections in the UWMP. **Figure 3-1** highlights these recent trends. Since 2015, potable water demand has been much lower than that anticipated in the UWMP.

[10] From the Napa Valley Wine Insider Digest, August 2021. Napa County recycled water was used at record levels amid the recent drought. Balance did not have access to reliable annual data since the 2015 UWMP was released.

[11] Raw water used for agricultural irrigation is included as part of potable demand in the UWMP.

Table 4 Recent potable and recycled water usage for American Canyon

	2015	2016	2017	2018	2019	2020
	(afy)	(afy)	(afy)	(afy)	(afy)	(afy)
Total potable water use[1]	2,968	2,572	2,558	2,667	2,418	2,665
Total projected potable water demand (2015 UWMP)[2]	2,976	3,062	3,148	3,233	3,319	3,405
Total City recycled water use[3]	**180**	**na**	**na**	**na**	**282**	**na**
Total projected recycled water demand (2015 UWMP)	385	509	634	758	883	1,007
Total water usage (actual)	**3,148**	**2,572**	**2,558**	**2,667**	**2,700**	**2,665**
Total projected water demand (2015 UWMP)	3,361	3,571	3,781	3,992	4,202	4,412

Notes:

[1] *Actual water usage from Napa County Flood Control and Water Conservation District SWP delivery accounting tables (provided by the City) plus agricultural raw water. Agricultural raw water use estimated to remain at 2015 level (56 AFY) through 2020, then be reduced to zero thereafter.*

[2] *Linear interpolation of 2015 usage and UWMP projected potable water demand for 2020.*

[3] *Actual recycled water usage, 2015 value obtained from the 2015 UWMP, 2019 value obtained from Napa Valley Wine Insider Digest, all other values not readily available.*

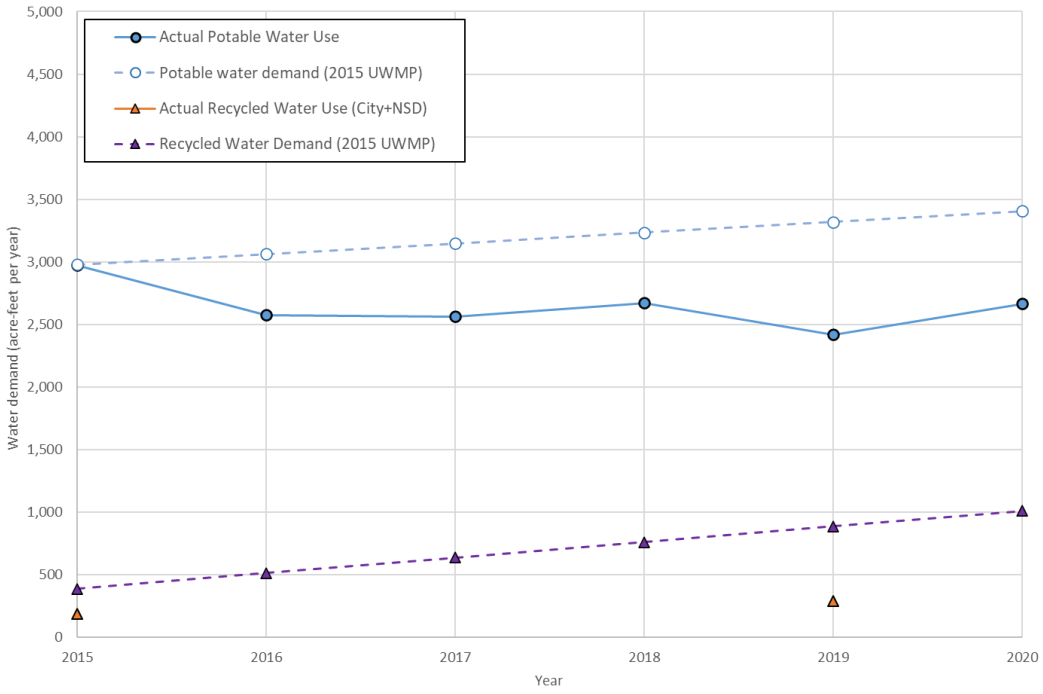

Figure 3-1 Potable and Recycled Water Demand vs. Actual Water Use

3.3.2 PROJECTED SYSTEM DEMAND

Projected Demand (2015 UWMP)

The 2015 UWMP projected future demand on a parcel-by-parcel basis relative to expected growth under the City's general plan. The analysis assumed that recycled water would be available to meet a portion of the total demand, with the remainder supplied by potable water. **Table 5** shows the water demand as presented in the 2015 UWMP.

Table 5 Projected potable, recycled, and total water demand for American Canyon through 2040, as presented in the 2015 UWMP

	2015 [5] (afy)	2020 (afy)	2025 (afy)	2030 (afy)	2035 (afy)	2040 (afy)
Projected potable water demand (UWMP) [1]	*2345*	*3,150*	*3,350*	*3,606*	*3,862*	*4,131*
Projected potable system losses (UWMP) [2]	*631*	*255*	*272*	*292*	*313*	*335*
Recycled water demand (UWMP) [3]	*385*	*1,007*	*1,146*	*1,351*	*1,862*	*1,862*
Total water demand (UWMP) [4]	**3,361**	**4,412**	**4,768**	**5,249**	**6,037**	**6,328**

Notes:

[1] *From 2015 American Canyon UWMP, Tables 4-3, excluding system losses.*

[2] *From 2015 American Canyon UWMP, Tables 4-3, system losses only*

[3] *From 2015 American Canyon UWMP, Tables 4-10*

[4] *Sum of potable demand, system losses, and recycled water demand, consistent with Table 4-10 in the 2015*

[5] *Actual values for 2015 presented in 2015 American Canyon UWMP, Tables 4-2. All other values are projected values.*

Unbilled Water Losses

The UWMP assumed that unbilled water losses[12] would be 7.5 percent for each year between 2020-2040. This is consistent with standards adopted by the California Urban Water Conservation Council (CUWCC), which provides that systems that experience greater than 10-percent losses annually undergo a water audit. In 2015, water delivery and water-use records indicate that system losses were 22 percent. The City is currently undertaking an aggressive response to the situation by replacing leaky services and water mains to reduce system loss. The City assumed it would reduce system losses to 7.5 percent of the total potable and raw water deliveries by 2020. In 2015, the City replaced more than 120 segments of residential services lines as part of its program to reduce distribution system losses.

[12] Referred to as "Unaccounted-for System Losses" in the UWMP, and "system losses" elsewhere in this WSA.

4 SUPPLY AND DEMAND COMPARISON

This section compares future City-wide water demand, to anticipated available supply under 'normal year,' 'single dry year,' and 'multiple dry year' scenarios. The scenarios presented herein have been summarized from the 2015 UWMP analysis for City-wide system planning.

The following analysis addresses potable and recycled water separately, as recycled water supply is considered reliable (and available at 100 percent of capacity) under all year-types. Reliability of potable water varies by year type as a percentage of contracted amount, as shown in **Table 6** and further described below.

Table 6 **Supply reliability for various American Canyon water sources**. Assumed percent of contracted amount for various year-type scenarios.

	2021-2040	Year Type				
Source	**Contracted or Available Volume**	**Normal Year**	**Single Dry Year**	**Dry year 1**	**Dry year 2**	**Dry year 3**
SWP (Table A allotment)	5,200	62%	5%	22%	22%	22%
Vallejo Permit Water [1]	500	100%	100%	100%	100%	100%
Vallejo Treated Water [1]	Varies [2]	100%	80%	80%	80%	80%
Vallejo Emergency Water [1]	500	0%	100%	100%	100%	80%
Groundwater [3]	n/a	--	--	--	--	--
American Canyon Recycled Water	n/a [4]	100%	100%	100%	100%	100%

Notes:

[1] *Percentages from 2015 UWMP, Table 7-4, 7-5, 7-6*

[2] *Contracted amount is 2,074 in 2015, 2,640 in 2020, and 3,206 2021-onward.*

[3] *Groundwater is not a source for City-wide supply.*

[4] *Recycled water is produced to meet demand; ultimately, maximum production capacity of City's recycled water system is expected to be 1,000 afy.*

4.1 Potable Water

Table 7 summarizes available potable water supply under 'normal year', 'single dry year', and 'multiple dry year' scenarios. As outlined in Section 2, the City's potable water supply relies exclusively on imported water, both from the SWP and through the City of Vallejo. A percentage of the full contracted amount is assumed for each source type under each scenario (**Table 6**, above). These percentages are based on guidance by DWR, analysis in the City's UWMP and the Vallejo UWMP. Resulting supply volumes for each source

under the various scenarios through 2040 are shown in **Table 7**. The supply and demand for potable water for each of the year-types is discussed below[13].

4.1.1 Normal Year

In a 'normal year', the City's 2015 UWMP assumes 'Table A' SWP deliveries would be 62 percent of the total contracted amount. Treated water from Vallejo water and raw Vallejo Permit water are assumed to be 100 percent available in normal years, consistent with the 2015 UWMP.

The UWMP concluded that future supply is available to meet anticipated demand in normal years through build-out in 2035, as does the analysis in this WSA (**Table 8**). Excess supply in normal years ranges from a low of 2,653 in 2040 to a high of 3,497 afy in 2025.

4.1.2 Single Dry Year

Under the "single-dry-year" scenario, the 2015 UWMP assumed SWP Table A deliveries to be curtailed to 5 percent of the contracted amount (see **Table 7 and Table 8**).

As discussed in Section 2.2, all water from Vallejo is considered a more reliable source than the City's SWP supply. The 2015 UWMP assumes that raw Vallejo Permit Water is available at 100 percent and Treated Vallejo Water are available at 80 percent of the contracted amount during single dry years. In addition, the full allotment of raw Vallejo Emergency Water (500 acre-feet) would be available under dry-year conditions. The analysis herein uses these same assumptions.

The 2015 UWMP shows that single-dry-year supply is not significantly currently constrained and the City will be able to reliably meet potable demand until the year 2030[14]. Single-dry-year deficiencies are anticipated starting in 2035 (**Table 8**). The City has several options available to resolve dry-year supply deficiencies, as described in Section 4.2.

[13] The analysis does not include adjustments for reduced demand of the Project relative to the assumptions in the UWMP for that parcel. As discussed in 3.2, the Project is expected to use 133.3 afy less than anticipated for those parcels in the UWMP, and will fund ZWF demand offsets of approximately 23.9 afy. Other recently completed projects or projects currently in the planning process may also affect projected demand, but have not been included in this analysis.

[14] Slight deficiencies are shown for dry-year supply in 2020 and 2030, but only by less than 2% of the total supply.

4.1.3 Multiple Dry Years

The multiple-dry-year scenario, as described in the UWMP, consists of three consecutive years of reduced water deliveries, though none are reduced to the same degree as the single-dry-year scenario[15]. The UWMP assumed that SWP Table A water would be reduced to 22 percent of the contracted amount for each of three years (see **Table 7 and Table 8**).

Raw Permit water are assumed to be available at 100 percent, and Treated water from Vallejo are assumed to be available at 80 percent of the contracted amount for years 1, 2, and 3 of the multi-year drought following the assumptions in the 2015 UWMP. Vallejo Emergency water is assumed to be available at the full contracted amount (500 acre-feet) for each of the three years of a multi-year drought, consistent with the 2015 UWMP.

The 2015 UWMP projects that water supply will exceed demand during a three-year drought through the full 2040 planning period (**Table 8**).

[15] The reference period used for the multi-dry-year scenario in the UWMP is the drought from 1990-1992. From a planning perspective, the UWMP assumed that a three-year drought is unlikely to include the "single dry-year" scenario.

4.2 Potable Water Deficiency Resolution

The above analysis compares potable water supply and normal-year demand, and projects supply shortages in several of the 'dry-year' and 'multi-dry-year' planning scenarios. This section describes a series of options available to the City to eliminate those shortfalls in order to provide reliable supply. Estimated SWP carryover water (see Section 4.2.1) would be sufficient to eliminate dry-year supply shortfalls, and could also be used in combination with drought demand reductions to further improve supply reliability.

4.2.1 SWP Carryover Water

If the City does not use its entire allotment of Table A water in a given year, the remaining water will carry-over to the following year, assuming there is adequate storage in SWP reservoirs to contain the excess supply[16]. Between 2015 and 2020, the City has stored between 35 and 2,600 acre-feet of carry-over water in a given year (**Table 9**), which has helped to meet demand during recent dry years. Because of the variability of carryover supply and the periodic "re-set" of the accounting when reservoirs are full, it is not considered a consistent yearly supply for planning purposes, but it does allow the City extra flexibility during droughts. As such, we have incorporated carry-over water into the analysis in this WSA.

We assume that 1,156 acre-feet of carryover water, the average over the last six years (**Table 9**), would be available at the beginning of a dry year and the first year of a multi-year drought. Projected excess normal-year supply ranges from 2,653 to 3,497 acre-feet for 2020-2040 (see **Table 8**), suggesting that the 1,156 acre-feet is a reasonable and somewhat conservative estimate for planning purposes[17]. In the second and third year of a multi-year drought, we assume that the remaining carry-over supply (assuming there is any) would continue to carry over to subsequent years to supplement supplies.

[16] In years when SWP reservoirs spill, the carry-over water is released, effectively re-setting carryover accounting to zero. Typically, however, ample storage is available in dry years.

[17] By definition, a single-dry-year would follow a normal or wet year, as would the first year of a three-year drought.

Table 9 **Recent SWP carryover water supply for the City of American Canyon.** Values from Napa County Flood Control and Water Conservation District SWP delivery accounting tables (provided by the City).

	2015	2016	2017	2018	2019	2020	Mean
Table A deliveries (% of total contract amount)[1]	25%	75%	100%	50%	85%	20%	59%
Available carryover water (remaining from previous year, in afy)[1]	876	1,087	127	2,210	35	2,600	1,156

Notes:

[1] From Napa County Flood Control and Water Conservation District SWP delivery accounting tables (provided by the City).

For example, in Single Dry Year scenario for 2035, 1,156 acre-feet would be available to meet the supply deficit of -350 acre-feet (from **Table 8**). The difference (806 af) would be available if there was another drought year. Under the above assumptions, the City would be able to meet projected supply deficiencies under all dry- and multi-dry-year scenarios within the planning period (2015-2040) through the use of available carry-over water.

4.2.2 Advanced Table A Program

A recent court settlement (Area of Origin Settlement[18], 2014), clarifies another potential mechanism for the Napa County FCWCD, the Solano County Water Agency, and Yuba City (along with subcontractors to those agencies, which includes American Canyon) to obtain water during dry periods. The Advanced Table A Program allows these agencies to 'borrow' against future SWP deliveries during times when annual deliveries are not sufficient to meet demand. The agreement requires that all Table A and Table A Carryover water be used prior to utilizing the Advanced Table A Program, but under those circumstances the City could request an advance of up to 949 af from future years' Table A allotments.

The projections in **Table 10** do not rely on the use of the Advanced Table A Program water to meet dry-year demand, as estimated Table A Carryover is enough to cover supply deficiencies for all scenarios. However, this Program provides an important tool available

[18] Superior Court of the State of California, County of Sacramento, Case No. 34-2008-00001633 8-CU BC GDS.

to the City should unforeseen circumstances result in significantly lower-than-expected carryover.

Table 10 Potable water deficiency resolution for dry- and multi-dry-year scenarios.

The table shows that all dry-year deficiencies can be met through carry-over water. In addition, the City has several other options available to help meet supply shortages during droughts.

Notes:

[1] *From Table 8*

[2] *Table A water not used in the prior year may be used in the following year, assuming storage is available; estimated from previous six years of carryover availability (see Table 9). Assume 1,156 af of available in a dry year and the first year of a multi-year drought. Remaining carryover after the first year of a drought is available in the second year, and remaining water after the second year is available in the third year of a drought.*

[3] *When the City exhausts its supply of carryover water, the City can "borrow" against future SWP deliveries, up to 949 af. Projected water shortages can be met solely through carryover supply, so no Advanced water is projected to be needed to meet demand.*

[4] *The City may chose to offset supply deficiency through demand reduction (drought restrictions) during dry periods. All supply deficiencies are projected to be satisfied through carryover water; restrictions are not likely to be required, but remain an option for the City, if needed; see Table 11 for projected estimated volume for drought conservation savings.*

[5] *The City also has the option to purchase additional water on the open market. While not required to meet long-term supply deficiencies the City may chose to use this option during droughts,*

[6] *Supply minus demand from above, plus additional supply available through carryover, "Advanced Table A", demand savings, and open market purchases.*

4.2.3 Drought-year Demand Reductions

It is important to note that the demand projections in the 2015 UWMP (as well as for the analysis in this WSA) were not explicitly adjusted for voluntary or mandatory water-use reduction measures that may be implemented in response to drought conditions[19]. The City has a Water Shortage Contingency Plan that outlines four stages of water demand reduction measures that could be utilized when water supply is constrained due to environmental or other conditions. The City projects demand reductions of 10/20/30/50 percent corresponding to each of the tiers, beginning with voluntary actions at Tier 1, and moving to increasingly restrictive mandatory measures for Tiers 2-4.

On June 1, 2021, in response to on-going statewide drought conditions, the City declared a Stage 1 drought emergency that called for a voluntary reduction from residential and commercial customers compared to the previous year. On July 20, 2021, the City declared a Stage 2 drought emergency, enacting mandatory water-use restrictions, requiring all water customers to reduce their water use by 20%. As of the end of August, 2021, water conservation measures have resulted in an 18 percent decrease from residential customers and 13 percent decrease from commercial customers.

Because estimated carryover water was sufficient to satisfy projected shortages, the supply and demand analysis in **Table 10** does not account for drought-year demand reduction. However, the City may choose to use these measures to provide additional flexibility during droughts. Assuming drought reductions of 13 percent, similar to what was achieved in 2014, the City could be expected to reduce demand in future years ranging between 305 af in 2015 and 537 af in 2040 (**Table 11**). While these volumes would not solely eliminate projected dry-year shortages, these measures could be used in conjunction with the above measures to provide additional buffer, as needed, if other supplies are unexpectedly curtailed. Stronger restrictions (level 3 or 4), could be used to achieve greater reductions if necessary, but are not likely to be needed.

[19] For the purposes of the UWMP and this WSA, demand is assumed to be the same in normal- and dry-year scenarios for a given planning period.

Table 11 **Projected drought-year demand savings.** Estimated drought conservation volume (potable demand reduction) that could be used during future droughts to help the City manage supply shortages. Volumes based on 13% savings achieved between 2013 and 2014.

	2015 (afy)	2020 (afy)	2025 (afy)	2030 (afy)	2035 (afy)	2040 (afy)
Projected normal-year potable demand[1]	2,345	3,150	3,350	3,606	3,862	4,131
Estimated drought conservation volume[2]	305	410	436	469	502	537

Notes:
[1] *From Table 5*
[2] *13% of potable demand.*

4.2.4 Open Market Purchases

As discussed in Section 2.4 the City has the option to purchase additional water from a variety of other sources on an as-needed and as-available basis. These potential purchases were not considered as a reliable long-term supply for the purposes of this WSA, though the City could choose to purchase additional supply in dry years when normal supplies are constrained. In fact, the City chose to utilize this option in 2015, and purchased 216 af of additional supply through the Dry Year Transfer and Yuba Accord Programs. As with the above options, Open Market Purchases can provide additional operational flexibility for the City during dry periods when other supplies are reduced.

4.3 Recycled Water

As discussed in Section 2.5, the City's recycled water system has a supply capacity of up to 1,271 acre-feet per year by 2035, and NSD has agreed to provide up to 591 acre-feet to supply the northern portion of the Airport Industrial Area (which is located within the City's water service area). Practically, however, the City produces recycled water to meet demand, as shown in **Table 8** (above). Because recycled water is derived from wastewater that is: 1) less susceptible to fluctuation due to climatic conditions, and 2) available in excess of the capacity of the recycled water system, recycled water is assumed to be 100 percent available during single- and multi-year-drought scenarios.

Table 8 presents recycled water supply versus demand for the 2015-2040 planning period under various year-type scenarios. Because recycled water use offsets water that would otherwise be delivered from limited potable or imported-water supply, it is in the City's

best interest to maximize recycled water use by way of increasing the number of recycled water users tied into the system.

The projections for recycled water use in the 2015 UWMP were, in effect, operational goals to maximize recycled water use. The UWMP projected 1,862 acre-feet of recycled water use by 2035. Recent recycled water use has been much lower than projected in the UWMP. For example, in 2019 water demand was projected to be about 883 AF, but the City only used 282 AF of recycled water. The City expects a significant expansion in the recycled water delivery system by 2035, allowing full use of the system by that time. Recycled water demand by sector is shown in **Table 12.**

Table 12 Summary of potential recycled water demand, by sector

Utility land-use classification	Potable offset demand[1] (afy)	Buildout demand[2] (afy)
Single-family residential	--	22.8
Multi-family residential	--	41.8
Commercial	3.4	49.7
Industrial	4.7	209.9
Institutional/Governmental	101.9	127.4
Landscape	69.4	119.5
Open Space	--	--
Watson Ranch	--	253.2
Recreation	--	204.3
Agricultural	68.1	173.2
Total	**247.5**	**1,201.9**

Notes:

[1] Adapted from GHD, 2016, Table 14. Projected demand used in the WSA analysis (Table 6) are lower than the numbers shown here in order to provide a conservative estimate of future demand.

[2] Buildout demand for Institutional/Gonvernmental assumes the American Canyon High School will halve existing demand by fixing suspected leaks in the irrigation system.

4.4 Summary

In summary, the analysis in this WSA shows that the City's water supply is sufficient to meet projected demand, in all years and under all normal-, dry, and multi-dry-year scenarios. The analysis shows that demand will exceed supply during some dry years, but the City will still be able to meet demand through the use of carryover SWP water, or through some combination of carryover SWP water, Advanced Table A Water, demand

reductions, and/or additional purchases on the open market. In addition, recycled water supply in the City is available to meet existing and projected demand, and available in sufficient volume to support non-potable uses at the Project site. Use of recycled water at the site will increase the City's utilization of this supply.

5 ZERO WATER FOOTPRINT POLICY

In October 2007, the City adopted a policy to regulate water use for new development. Under this Zero Water Footprint (ZWF) policy, new accounts are required to offset the proposed project's potable water use through off-site water conservation measures, conversion of off-site potable irrigation to recycled water, on-site demand reduction (relative to existing use), or by acquiring additional supply. The City has provided a list of potential conservation, repair, and other projects within the service area that could be used as offsets for new service accounts. In 2011, the City adopted an additional policy that further refined the offset options available to meet the ZWF requirements.

5.1 Project ZWF Compliance

The proposed Project is required to comply with the City's ZWF policy, and will offset all of its potable water demand. The Project will offset its potable water demand by implementing several items off of the City's offset "toolbox", likely to include a combination of off-site landscape irrigation water conversion and conversion of existing potable water customers.

Anticipated potable water use for the Project, once completed, would be 23.9 afy. ZWF offset totals will be required to be at least that amount.

5.2 City-wide Compliance

On the whole, compliance with the City's ZWF policy should essentially result in no net increase in potable water demand[20] as new projects are built within the City's water distribution area. The effect of this policy was not explicitly accounted for in the long-term potable demand projections in the 2015 UWMP or for this WSA. However, two of the main ways that projects can reach compliance with the ZWF policy would be through funding conversion of irrigated landscape areas to recycled water, and improving the efficiency of the City's water distribution system (reducing system losses). The analysis in this WSA has included projections of both recycled water system expansion and reduced potable water losses that would, at least in part, be funded through implementation of the ZWF policy.

[20] Or alternatively, offset increases in demand with increased volume of reliable supply.

6 LIMITATIONS

This technical report was prepared in general accordance with the accepted standard-of-practice existing in Northern California at the time the analyses were performed. No other warranty is made or implied. Readers are asked to contact us if they have additional relevant information, or wish to propose revisions or modified descriptions of conditions, such that the best data can be applied at the earliest possible date.

Mr. Paul Fuchslin
Director of Engineering
Solano Irrigation District
810 Vaca Valley Pkwy Suite 201
Vacaville, CA 95688

SUBJECT: Proposed Water Usage for the Suisun Logistics Center and Highway 12 Logistics Center Projects – Suisun City – CA.

The intent of this memo is to provide clarity as to the yearly anticipated water usage demand for both proposed Buzz Oates City of Suisun City projects (Suisun Logistics Center & Highway 12 Logistics Center).

High-Cube Warehouse and Distribution buildings are not a water-intensive use, especially when compared to other heavy industrial uses. Most of the water demand for High-Cube Warehouse and Distribution comes from landscape irrigation. Buzz Oates intends to minimize landscape irrigation, further reducing anticipated water demand.

We requested water meter data for similar buildings developed, constructed, owned, and operated by Buzz Oates from the City of Fairfield Water Department to provide accurate water usage loads.

Michael Hether, Assistant Public Works Director provided the attached usage data that spans approximately 5 years, 7 months. The annual acre-foot usage was calculated as an aggregate spanning the entire duration of building operation by utilizing the average daily usage data for domestic, irrigation, and fire suppression demands. Broken down, this equates to 0.29228 acre feet per year per developable acre of water demand.

Total water demand equals approximately +/-62 acre-feet when applied to the proposed City of Suisun City projects. See below breakdown. I have also attached the usage data provided by the City of Fairfield for reference.

ADRESS	Sq. Ft.	Acres	Yearly Acre Feet	Acre Feet Per Developable Acre
2975 Cordelia Rd.	473,136	24.25	0.840132626	
2925 Cordelia Rd.	318,402	18.73	10.05492075	
2875 Cordelia Rd.	176,760	9.32	3.022470217	
2825 Cordelia Rd.	36,950	3.99	2.534983094	
		56.29	16.45	**0.29228**

Suisun Logistics Center — 120 developable acres (x 0.29228) = 35.0736

Highway 12 Logistics Center — 93 developable (x0.29228) = 27.182

TOTAL — **62.255 ANTICIPATED YEARLY ACRE-FOOT USAGE**

RAK CIVIL ENGINEERS
ROBERT A. KARN & ASSOCIATES, INC.

SECTION 1: INTRODUCTION

In accordance with California Environmental Quality Act (CEQA) Guidelines Section 15088, the City of American Canyon (Lead Agency) has evaluated the comments received on the Giovannoni Logistics Center Project Draft Environmental Impact Report (Draft EIR). Pursuant to CEQA Guidelines Section 15132, this Final EIR includes a list of persons, organizations, and agencies that provided comments on the Draft EIR; responses to the comments received regarding the Draft EIR; and errata, or revisions to the Draft EIR; as well as a Mitigation Monitoring and Reporting Program (MMRP) for use by the City of American Canyon during its review.

This document is organized into five sections:

- **Section 1—Introduction.** Provides an introduction to the Final EIR.
- **Section 2—Master Responses.** Provides a single, comprehensive response to similar comments about a particular topic.
- **Section 3—Responses to Written Comments.** Provides a list of the agencies, organizations, and individuals who commented on the Draft EIR. Copies of all of the letters received regarding the Draft EIR and responses thereto are included in this section.
- **Section 4—Responses to June 23, 2022, Planning Commission Meeting Comments.** Provides a list of the speakers who commented on the Draft EIR, a summary of their comments, and responses thereto are included in this section.
- **Section 5—Errata.** Includes an addendum listing refinements and clarifications on the Draft EIR, which have been incorporated.

The Final EIR includes the following contents:

- Draft EIR (provided under separate cover)
- Draft EIR Appendices (provided under separate cover)
- Responses to Written Comments on the Draft EIR (Section 3), Responses to Planning Commission Meeting Comments (Section 4), and Errata (Section 5)
- Mitigation Monitoring and Reporting Program (provided under separate cover)

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 2: MASTER RESPONSES

Master responses address similar comments made by multiple public agencies, businesses, organizations, or individuals through written comments submitted to the City of American Canyon. Master responses are provided in the order in which they are referenced in the responses in Section 3. The master responses are intended to provide thorough responses to all of the individual comments that raised the same issue or very similar issues.

2.1 - List of Master Responses

- Master Response 1—Impacts to Swainson's Hawk/Golden Eagle Foraging Habitat
- Master Response 2—New "North" Fire Station
- Master Response 3—Buildout Assumptions
- Master Response 4—Vehicle Miles Traveled

2.2 - Master Responses

Master Response 1—Impacts to Swainson's Hawk/Golden Eagle Foraging Habitat

Summary of Relevant Comments

Both the California Department of Fish and Wildlife (CDFW) and Scott Cashen stated that the proposed project would result in the loss of Swainson's hawk foraging habitat and this impact should be mitigated in accordance with CDFW mitigation guidelines. Mr. Cashen also provided similar comments about the loss of golden eagle foraging habitat. The CDFW noted that the Draft Environmental Impact Report (Draft EIR) identifies that the proposed project would remove Swainson's hawk foraging habitat but does not specify the acreage. The CDFW also stated that the approximately 45 acres of wetlands that would be preserved by the proposed project may not be sufficient to mitigate for the loss of Swainson's hawk foraging habitat, and the presence of suitable Swainson's hawk foraging habitat near the site does not negate the need to mitigate for permanent removal of foraging habitat for this species.

Response

Swainson's Hawk

The development of Phase 1 would permanently impact approximately 68.8 acres of Swainson's hawk foraging habitat, and the development of Phase 2 would permanently impact approximately 85.9 acres of Swainson's hawk foraging habitat.

Draft EIR Section 3.3, Biological Resources, page 3.3-24 acknowledges that development of the proposed project would remove some foraging area for this species, but also indicated that the proposed project would also provide and preserve in perpetuity approximately 45 acres of wetlands that would include habitat currently suitable for foraging by the Swainson's hawk as indicated by the observation of a Swainson's hawk foraging in the site in spring 2021. In addition, the Draft EIR acknowledges the Napa Logistics Park Project has preserved 37 acres of grassland and wetlands in perpetuity that provides foraging habitat for Swainson's hawk and that there are several large open

space preserves within 2 and 5 miles of the project site that, combined, provide approximately 2,000 acres of suitable foraging habitat for the Swainson's hawk within a 10-mile radius of the project site. This demonstrates that, based upon the limited number of known Swainson's hawk to occur within a 10-mile radius of the project site, and with the acreage of existing foraging habitat currently protected, there is more than sufficient foraging habitat near the project site. Accordingly, the proposed project would not result in significant impacts to foraging habitat nor affect the nesting populations of Swainson's hawk near the project site either directly, indirectly, or cumulatively. Therefore, no mitigation is warranted for Swainson's hawk foraging habitat. Importantly, the operative significance thresholds for impacts to Swainson's hawk are (i) whether the proposed project would have a substantial adverse effect on the species, either directly or through habitat modifications, or (ii) whether the proposed project would substantially reduce the number or restrict the range of the species. Although the proposed project would result in a net loss of foraging habitat, such a net loss occurring in the particular area in which the project site is located, the proposed project would not cause either a substantial adverse effect on the species, a substantial reduction in its numbers, or a substantial restriction of its range. There is no need to "net out the impact of a proposed project" for that impact to be less than significant. (See *Save Panoche Valley v. San Benito County* (2013) 217 Cal.App.4th 503, 529.)

CDFW's Life History Account for the Swainson's hawk indicates that this species feeds on small mammals, amphibians, reptiles, and birds, and soars and low and high levels in search of prey. The Life History Account also indicates that the Swainson's hawk can be found in riparian habitat, sparsely vegetated flatlands, open desert, grassland, or cropland containing scattered large trees or small groves. In sum, Swainson's hawk is a hardy species that can survive on a range of prey in a variety of very different habitats throughout California; it does not only occur in southern Napa County. The relatively small loss of foraging habitat on the project site would not affect the range of the species or cause the loss of substantial numbers of individual hawks.

Geoff Monk of Monk & Associates, one of the biological consulting firms that prepared the biological resources analysis, worked extensively with the Swainson's hawk over four decades, and banded many nestlings of this species. The Swainson's hawk is a California designated threatened species protected pursuant to the California Endangered Species Act (CESA). To obtain known/recorded information for the occurrence of nesting Swainson's hawk nearest the project site, Monk & Associates completed a record search in the California Natural Diversity Database (CNDDB). It should be noted that all species of *Buteo* frequently change nesting locations from year to year, and may reuse a nest site in successive years or may move to a different nest site for one year and then back to nest sites used previously. Raptor biologists generally regard nests that are currently in use to be the "active nests," while nests that are used in successive years or in alternate years are regarded as "alternate nest sites." CESA (FGC § 2050 *et seq*.) and Fish and Game Code statutes that protect nesting birds (and raptors) (FGC §§ 3503, 3503.5, 3513, and 3800) would afford protections only to those nests that are currently in use by the nesting birds. Alternate nesting sites that are not occupied are afforded no protections pursuant to CESA or the Fish and Game Codes that protect nesting birds.

In 1979, Dr. Peter Bloom published a report estimating that the historical baseline for Swainson's hawk breeding pairs in California was somewhere between 4,284 to 17,136. Dr. Bloom's 1979 report

also estimated only 375 (±50) breeding pairs remained in California, showing a rapid decline in population at the time, as compared to the historical baseline. Dr. Bloom's report noted that breeding pairs were heavily concentrated in the Central Valley, the Great Basin area of northeastern California; as well as a few concentrated Swainson's hawk territories located in Shasta Valley, the Owens Valley, and the Mohave Desert.[1] In 1988, a CDFW-led survey effort revealed no material change in Swainson's hawk distribution from the 1979 Bloom report. The 1988 effort estimated 430 pairs in the Central Valley and a Statewide estimate of 550 breeding pairs. In 2005, the CDFW conducted a Statewide survey estimating 2,081 breeding pairs.[2] The 2005 survey showed a steady increase in Swainson's hawk breeding pair population when compared to the 1979 breeding pair estimate.

In 2005, Dr. Bloom noted that the Swainson's hawk population in California (and throughout North America) was suffering from acute poisoning from grasshopper insecticide use in Argentina applied directly to Swainson's hawk's gregarious migration roosts in Argentina. Detrimental Argentinian insecticide use has largely stopped in recent years, and the Swainson's hawk nesting population in California has grown significantly. In 2007, the CDFW estimated 1,948 Swainson's hawk breeding pairs in California's Central Valley, with most of the population occurring in the area from Stanislaus County north to Butte County.

Dr. Bret Furnas' 2022 study titled "*Rapid Growth of the Swainson's Hawk Population in California Since 2005*"[3] estimated the total Statewide population of 18,810 breeding Swainson's hawk breeding pairs based on survey data collected in 2005, 2006, 2017, and 2018. The research group, which included Dr. Bloom, concluded that California's Swainson's hawk summering population grew between 2005 and 2018 at the rapid rate of 13.9 percent per year. It should also be noted that the current estimate of 18,810 breeding pairs is extraordinary given Dr. Bloom's 1979 estimate of 375 nesting pairs in the State. The 2022 estimate is within the range of the historical baseline that Dr. Bloom estimated in 1979 prior to the population decline.

The Swainson's hawk nesting distribution now occurs in many areas where the Swainson's hawk has not been known to nest for decades, if ever. Napa County, while considered within the historic distribution of the Swainson's hawk, was not known to support any nesting sites for this hawk in the 1970s or 1980s. Similarly, the nesting population now extends into east Contra Costa County where nesting previously had not been recorded for many decades. Other nesting population recovery includes Southern California in the Antelope Valley and in Kern County.

[3] Furnas, Brett J., David H. Wright, Erin N. Tennant, Reagen M. O'Leary, Michael J. Kuehn, Peter H. Bloom, and Carie L. Battistone. 2022. Rapid Growth of the Swainson's Hawk population in California since 2005. Ponithological applications, Volume 124, Issue 2. May 2022.

Widespread nesting recovery documented by Furnas et al. (2022)[4] has yet to be incorporated into CDFW policy and/or in records kept within the CNDDB.[5] Accordingly, the "Staff Report Regarding Mitigation for Impacts to Swainson's Hawks (*Buteo swainsoni*) in the Central Valley of California" (Staff Report), besides being geographically inappropriate for the proposed project in Napa County, is also not relevant to current nest territory expansion of the Swainson's hawk population into Napa County and elsewhere in the State. Thus, this document is not appropriately used as a basis for determining mitigation ratios for impacts to annual grassland in Napa County. The Staff Report recommends mitigation for projects that impacts foraging habitat within 10 miles of an "active" Swainson's hawk nest (as defined by the CDFW Staff Report). For the reasons provided previously, this mitigation requirement does not reflect the current population expansion of the Swainson's hawk in California, and its use is geographically limited.

It is noteworthy that other raptors that were State and federally listed when the Swainson's hawk was State listed in 1983 such as the bald eagle (*Haliaeetus leucocephalus*) and the peregrine falcon (*Falco peregrinus*) have been delisted (i.e., removed from protections provided by both CESA and the federal Endangered Species Act). The federal government conducted routine census surveys for these species and determined that the nesting populations of these species had fully recovered, and, thus, protection pursuant to the Endangered Species Act was no longer warranted. The CDFW followed these delisting efforts. In contrast, the Swainson's hawk was never federally listed, and as the State of California does not have a recovery plan for the Swainson's hawk, there is no guideline for what constitutes recovery. In addition, the Swainson's hawk has not been counted to the extent that federal listed raptor species were. Thus, mitigation prescriptions developed more than 25 years ago are very likely outdated today.

The proposed 45-acre Wetland Preserve with its seasonal wetlands would be available to provide foraging habitat for the Swainson's hawk in perpetuity. Additionally, less than 2 miles from the project site are 620 acres of dedicated open space (Newell Open Space) that are also preserved in perpetuity. The Newell Open Spaces appears to primarily comprise annual grassland with discrete areas of oak woodland and riparian woodland. Further, the Newell Open Space abuts other dedicated open space preserves, including the 1,039-acre Lynch Canyon Open Space Park and the American Canyon 308-acre California red-legged frog preserve. Combined, these open spaces dedicate over 2,000 acres of open space that can be used for foraging by the Swainson's hawk because the open space supports the small mammals, amphibians, reptiles, and birds on which Swainson's hawks prey. This demonstrates that based on the limited number of Swainson's hawk records in Napa County, there is more than sufficient foraging habitat in the area that will be preserved in perpetuity to support actively nesting hawks and that further provide foraging habitat for other raptors of concern, specifically golden eagles and western burrowing owls. Accordingly, the proposed project would not result in significant impacts to foraging habitat either directly, indirectly, or cumulatively. The net loss of foraging habitat resulting from the proposed project will not cause either a substantial adverse effect on the species, a substantial reduction in its numbers, or a

[4] Furnas, Brett J., David H. Wright, Erin N. Tennant, Reagen M. O'Leary, Michael J. Kuehn, Peter H. Bloom, and Carie L. Battistone. 2022. Rapid Growth of the Swainson's Hawk population in California since 2005. Ponithological applications, Volume 124, Issue 2. May 2022.

substantial restriction of its range. Construction of the proposed project would not be expected to affect the nesting population of Swainson's hawk known from Napa County. Accordingly, additional preservation over and above the 45-acre Wetland Preserve is not warranted for the proposed project. Thus, there is no potential for significant indirect or cumulative impacts associated with habitat for Swainson's hawk in this area and the proposed project would not add to any such impact.

Golden Eagle

CDFW's Life History Account indicates that the golden eagle feeds on small mammals, reptiles, and birds, as well as carrion. The Life History Account also indicates that the golden eagle forages in open terrain, including grasslands, deserts, savannas, and early successional stages of forests. Like the Swainson's hawk, the golden eagle is a hardy species that can survive on a range of prey in a variety of very different habitats throughout California; it does not only occur in southern Napa County.

Accordingly, for the same reasons the proposed project would not result in an indirect or cumulative loss of Swainson's hawk foraging habitat, it would also not result in a significant indirect or cumulative loss of golden eagle foraging habitat.

Master Response 2—New "North" Fire Station

Summary of Relevant Comments

The American Canyon Fire Protection District (ACFPD) indicated that the proposed project, along with other planned development, would trigger the need for a new "North" fire station and related apparatus. The Sentinels of Freedom, a 501(c3) nonprofit organization, indicated that it owns a 25.44-acre vacant property adjacent to Napa Logistics Park and would like to offer to sell the site to the City of American Canyon for the development of a fire station and training center.

Response

As the ACFPD letter indicates, the Giovannoni Logistics Center Project and other planned projects in the northern portion of American Canyon create a need for a new fire station. The need is not solely caused by the Giovannoni Logistics Center Project. At the time of Final EIR publication, the new "North" fire station is conceptual in nature and no facility planning has occurred. The ultimate fate of the potential facility therefore remains speculative. (See California Environmental Quality Act [CEQA] Guidelines, § 15145 [lead agencies need not address speculative impacts].)

The letter from ACFPD identified a number of possible "mitigation measures" for addressing ACFPD's "annual operating deficit." The City notes in response that "mitigation" is not the right word to describe any fair share funding that the project proponent may contribute to ACFPD's operations. Under CEQA, the proper focus of service-related impacts is on the physical effects of the construction of new or expanded facilities to provide services. Any inadequacy in the provision of actual services due to funding shortfalls is not a CEQA impact triggering mitigation. (See *City of Hayward v. Board of Trustees of the Cal. State University* (2015) 242 Cal.App.4th 833, 843 ["[t]he need for additional fire protection services is not an environmental impact that CEQA requires a project proponent to mitigate"]; *Goleta Union School Dist. v. Regents of Univ. of Cal.* (1995) 37 Cal.App.4th 1025, 1031–1034 [school overcrowding attributable to new development is not an environmental effect subject to CEQA, though the physical effects of new facility construction to

serve new students would be]; and CEQA Guidelines, Section 15131, subdivision (a) ["[e]conomic or social effects of a project shall not be treated as significant effects on the environment"]).

The Sentinels of Freedom property was evaluated as a potential alternative location for the proposed project in Chapter 5, Alternatives to the Proposed Project. As discussed in Draft EIR Chapter 5, Alternatives to the Proposed Project, page 5-17, the site was determined to be too small to support a 2.4-million-square-foot logistics center. However, the property is designated for "Industrial" use by the Napa County General Plan, zoned "Business/Industrial" by the Napa County Airport Industrial Area Specific Plan, and is within both the City of American Canyon's Sphere of Influence (SOI) and Urban Limit Line (ULL). From a preliminary perspective, the Sentinels property may be a suitable location for a new fire station but more due diligence would be required to confirm its suitability.

Regardless, at the time of Final EIR publication, no decisions had been made regarding the acquisition of the Sentinels property or any other property for a new "North" fire station. Hence, the development of a new fire station is outside the scope of the Draft EIR.

Master Response 3—Buildout Assumptions

Summary of Relevant Comments

Both Golden State Environmental Justice Alliance (GSEJA) and Napa-Solano Residents for Responsible Growth (NSRRG) alleged that the Draft EIR used inconsistent buildout assumptions. Both organizations first cited a statement in Draft EIR, Chapter 2, Project Description, page 2-9, to the effect that the Draft EIR assumes that Phase 1 would buildout first followed by Phase 2 and then noted a subsequent statement indicating that, as a practical matter, the proposed project would likely buildout over a period of years, if not decades. NSRRG alleged that a prolonged construction schedule that extends over several years (multiple nesting seasons, multiple "rainy seasons") increases the potential for construction-related impacts to aquatic resources.

Response

The Draft EIR provided the following statement on page 2-9 in Chapter 2, Project Description:

> For the purposes of providing a conservative, worst-case scenario, this Draft EIR assumes that Phases 1 and 2 would be developed concurrently over a period of 18 months.
>
> As a practical matter, the proposed project would buildout over a period of years or decades. Phase 1 would be developed first, followed by Phase 2.

The applicant has indicated that actual buildout is expected to occur as follows:

- Phase 1 is permitted through the resource agencies.
- Phase 1 is mass graded; building pads and wetland restoration areas are created.
- Phase 1 is developed with buildings, either spec or with known end user(s).
- Phase 2 is permitted through the resource agencies.
- Phase 2 is mass graded; building pads and wetland restoration areas are created.
- Phase 2 is developed with buildings, either spec or with known end user(s).

Given the uncertainty regarding the timing of each of these stages, using a "front loaded" buildout horizon allowed the Draft EIR to disclose the maximum amount of construction and operational emissions that could be emitted. The California Emissions Estimator Model (CalEEMod) air emissions model is predicated on both the construction equipment and operational vehicle fleet getting cleaner over time. Thus, "front loading" buildout for the purposes of modeling reasonable worst-case emissions is consistent with CEQA principles, which disfavor the understatement of environmental impacts. Moreover, this was the same approach used in the Napa Logistics Park Phase 2 and Napa Airport Corporate Center EIRs. Furthermore, this statement reflects observations of how buildout of the neighboring Napa Logistics Park and the Green Island Business Park has occurred.

Likewise, if a longer buildout schedule were used (i.e., 10 years), the net effect would be to reduce the amount of construction and operational emissions attributable to the project because it would benefit from a cleaner fleet. Moreover, such an approach would also require a more complicated multi-phased analysis that would involve considerable speculation and would require a significant amount of time and effort to complete and which may not yield any more meaningful, probative information about project impacts.

NSRRG is speculating in assuming that a prolonged buildout schedule would result in greater impacts to aquatic resources. In fact, however, the approach taken in the EIR has created a more conservative, reasonable worst-case approach. As indicated previously, Phase 1 and Phase 2 would be mass graded following resource agency permitting. Building pads and wetland restoration areas would be created. Furthermore, the applicant is required by Mitigation Measure (MM) HYD-1a to implement a Storm Water Pollution Prevention Plan (SWPPP) and Best Management Practices (BMPs) during grading and construction. Those protections would remain in place in the interim period between mass grading and building completion. Thus, it is speculative to assume that a prolonged buildout schedule would result in greater impacts to aquatic resources.

Lastly, the statement on page 2-9 about "a period of 18 months" has been corrected to "a period of 20 to 24 months" and change is noted in Section 5, Errata. The change does not materially affect any conclusions of the air quality analysis since it used a 20-month buildout schedule.

NSRRG also alleged that a prolonged construction schedule that extends over several years increases the potential for construction-related impacts to aquatic resources and nesting birds. As stated above in the response to emissions, given the uncertainty regarding the timing of each of these stages, using a "front loaded" buildout horizon allowed the Draft EIR to disclose the maximum amount of impacts to aquatic resources wetland impacts.

Constructing Phase 1 and 2 concurrently over an 18-month period would impact 0.496-acre of wetlands for Phase 1 and 3.7 acres of wetlands for Phase 2 for a total of 4.196 acres of wetlands, which is the worst-case scenario, meaning the maximum acreage of wetland impacts would be 4.196 acres. The "worst-case scenario" assumption is not linked to the number of months it would take to complete each Phase but rather is a function of the acreage of wetland impacts. Phase 2 wetland impacts were assessed based on a full buildout with a maximum impact of 3.7 acres of wetlands. It is possible that, once Phase 2 has gone through the entitlement process, the site plan may be modified to reduce impacts to under 3.7 acres, just as Phase 1 has avoided impacts.

It should be noted that, if construction takes 18 months to complete or longer, all mitigation measures outlined in the Draft EIR would apply for the entirety of the construction period. Therefore, there is no basis to assume new impacts would occur if Phases 1 and 2 take two months to complete or 24 months. It should also be noted that the project will occur over at least two nesting periods, and if birds do nest in the project vicinity and construction has commenced, it should be assumed that the nesting bird(s) are habituated to the ambient level of noise and disturbance emanating from the project site. Therefore, a prolonged construction period that extends beyond 18 months would not increase the chance of construction-related impacts. Regardless, for consistency and to address the commenters concerns, MM BIO-4 was revised to require additional pre-construction breeding bird surveys if construction activities are discontinued for more than 7 days.

Master Response 4—Vehicle Miles Traveled

Summary of Relevant Comments

Both GSEJA and NSRRG alleged that the Vehicle Miles Traveled (VMT) analysis provided no justification for the threshold of 23 miles per employee, and improperly used the California Statewide Travel Demand Model. NSRRG referenced the VMT analysis for a 217,000-square-foot wine distribution warehouse (SDG Commerce 217 Distribution Center Project) less than 2 miles away, which employed a different methodology and thresholds. GSEJA also argued that the VMT analysis was flawed due to its failure to account for non-employee heavy-duty truck trips in the analysis.

Response

To preface this response, VMT is a relatively new area of CEQA, having only been added to the Appendix G Checklist in late 2018 and only applying to environmental documents issued on or after July 1, 2020. Similar to the early years of greenhouse gas (GHG) emissions being introduced to the environmental review process, there is a range of guidance—sometimes conflicting—as to how to evaluate VMT. Likewise, many lead agencies have not adopted their own VMT thresholds or issued any guidance regarding methodology, which is the case for the City of American Canyon. Furthermore, the Napa-Solano regional traffic model is limited in its abilities to calculate project-level VMT. Lastly, there is very little in the way of guidance for evaluating VMT for industrial or warehousing projects. With these factors in mind, W-Trans evaluated VMT with the best information available using the most relevant guidance.

Giovannoni VMT Analysis

Guidance contained in the *Technical Advisory on Evaluating Transportation Impacts in CEQA*, 2018, California Governor's Office of Planning and Research (OPR) (OPR Technical Advisory) was used in selecting an appropriate VMT threshold of significance for the proposed project. While this publication provides no specific direction on the threshold that should be applied to warehouse-related land uses, it does indicate that office-related land uses should use a metric based on automobile commute VMT per employee, with a significance threshold tied to the regional average VMT per employee. Basing the proposed warehouse project's VMT analysis on a commute VMT per employee performance metric was deemed appropriate since the employee automobile commute characteristics of a warehouse project are similar to those produced by an office project. The term

"regional" refers to the Metropolitan Planning Organization (MPO) boundary that the site is located within; for American Canyon this is the nine-county Bay Area overseen by the Metropolitan Transportation Commission (MTC). This approach to defining "regional" is consistent with direction provided by OPR in an online document entitled, "SB 743 Frequently Asked Questions." That document defines "regional" as "the full geography within the jurisdictional borders of a Metropolitan Planning Organization or a regional transportation planning agency." Accordingly, the proposed project's VMT significance threshold was based on an automobile commute VMT per employee performance metric that that was compared to the nine-county Bay Area regional average.

With respect to the use of a significance threshold for commute VMT per employee that is equal to the regional average, rather than 15 percent below the regional average as suggested in the OPR Technical Advisory for office uses, thresholds adopted by other jurisdictions, including Sacramento County and San José, were reviewed as noted in the project's Draft EIR. As discussed in the *Transportation Analysis Guidelines*, County of Sacramento, 2020, "placing industrial land uses in less urban areas characterized by having higher VMT per employee allows land in efficient VMT areas to be more effectively utilized as high-density residential and commercial or office/business professional uses. This threshold is consistent with achieving an overall reduction in regional VMT, as it recognizes that industrial uses, which are relatively lower total VMT generating uses, are most appropriate in areas that have a lower potential to reduce VMT because it results in more available land within areas with a high potential to achieve VMT reductions available for more dense development." Note that Sacramento County applies the same significance threshold for both industrial and warehousing uses. San José applied similar logic in developing its VMT thresholds for industrial and warehousing uses, which are also equal to the regional average VMT per employee.

It is also noted that during "office hours" webinars conducted by OPR in summer 2020, OPR staff acknowledged that industrial/warehousing projects are different from traditional "office" developments, and OPR offered the opinion that jurisdictions looking to establish significance thresholds for such uses may benefit from reviewing the thresholds set by San José. The proposed project's applied VMT significance threshold was developed using the evidence provided by these sources, including the overall premise that locating industrial and warehouse projects in less VMT-efficient areas can play an important role in reducing the community's *overall* VMT, helping to achieve established GHG reduction targets.

Notwithstanding the foregoing, it is worth noting that, although the Draft EIR used a threshold of commute VMT per employee that is equal to the regional average rather than 15 percent below the regional average as suggested in the OPR Technical Advisory for office uses, the VMT for the proposed project is actually substantially more than 15 percent below regional average. As shown in Draft EIR on page 3.12-18, Table 3.12-9, Vehicle Miles Traveled Summary, the regional average VMT per employee is 23.0 miles, while the proposed project's VMT per employee is 16.24 miles, which is roughly 29 percent below the regional average. Thus, the Draft EIR would have reached the same conclusion with respect to the VMT-related impacts of the proposed project—namely, that they were less than significant—even if the City had used the OPR-recommended threshold of 15 percent below the regional average for office projects.

The California Statewide Travel Demand Model (CSTDM) was determined to be the best available source of traffic analysis zone (TAZ)-level VMT data when the proposed project's Notice of Preparation (NOP) was released (January 2021). While a model including the Napa-Solano region exists, it was deemed inappropriate for use in the proposed project's VMT analysis because it truncates vehicle trip lengths at the county line, thereby resulting in an incomplete calculation of a project's potential trip lengths.

Since the Napa-Solano travel demand model does not account for full trip lengths and is not capable of calculating a regional commute VMT per employee metric tied to the nine-county Bay Area used to establish the VMT significance threshold, it was necessary to research other appropriate sources for this value. The City of Vallejo Transportation Impact Analysis Guidelines were deemed to be an appropriate source, not only because of Vallejo's proximity to the proposed project, but because Vallejo faces the same constraints as American Canyon and Napa County in establishing VMT metrics and averages using the Napa-Solano model.

With respect to the use of a different VMT threshold of significance for a nearby distribution center, as discussed below, that project's Mitigated Negative Declaration (MND) has not been accepted by the City of American Canyon. Accordingly, it would be inappropriate to compare the proposed project's VMT methodology and thresholds to those applied in evaluating that project.

SDG Commerce 217 Distribution Center Project

The SDG Commerce 217 Distribution Center Project was initially evaluated in an MND issued in December 2020. Following receipt of comments, the City of American Canyon recirculated the MND in April 2021. Following another round of comments, the applicant requested that the City withdraw consideration of the MND in July 2021. The applicant then elected to proceed with the preparation of an EIR, which has not yet been publicly released at the time of Final EIR publication. It should be noted that neither FirstCarbon Solutions (FCS) nor W-Trans had any involvement with the SDG Commerce 217 Distribution Center Project MND and, thus, have no insights into the decision-making process concerning the VMT analysis.

The Giovannoni Logistics Center EIR did not tier from or rely upon any of the SDG Commerce 217 Distribution Center Project MND's conclusions. Furthermore, the SDG Commerce 217 Distribution Center Project MND has no legal significance given that it was withdrawn from consideration. Lastly, lead agencies have the discretion to use different methodologies and thresholds on a project-by-project basis so long as they are supported by substantial evidence. For these reasons, the VMT methodologies and thresholds used in the SDG Commerce 217 Distribution Center Project MND do not have any bearing on Giovannoni Logistics Center EIR.

Medium- and Heavy-Duty Truck Trips from Logistics operations

As explained above, the VMT analysis in the Draft EIR focused on employee trips and not on truck trips associated with the anticipated functioning of the proposed project's logistics operations. This focus on employee trips in cars and light-duty trucks rather than incoming and outgoing trips by medium- or heavy-duty trips associated with logistics operations is consistent with direction provided by OPR and with the legislation (Senate Bill [SB] 743 of 2013) that authorized OPR and the California Natural Resources Agency to promulgate what became CEQA Guidelines Section 15064.3.

As the Draft EIR explained on page 3.12-17, the OPR Technical Advisory defines "automobile," as the term is used in Section 15064. 3, as referring to "on-road passenger vehicles, specifically cars and light trucks." (Technical Advisory, page 4.) Thus, OPR understands the requirement to address transportation VMT as not reaching heavy-duty trucks. The focus on automobiles and not on heavy-duty trucks is consistent with the policy focus behind the elimination of automobile delay as a factor in assessing the significance of transportation-related impacts, as set forth in SB 743. Public Resources Code Section 21099, subdivision (b)(1), directed the OPR and California Natural Resources Agency to develop alternative significance criteria that would "promote the reduction of greenhouse gas emissions, the development of multimodal transportation networks, and a diversity of land uses." Accounting for heavy-duty trucks engaged in interstate commerce would not contribute to these policy goals, as local and State governments have little or no control over interstate commerce involving trucking.

Furthermore, as the Draft EIR explained in its discussion of environmental effects associated with greenhouse gas (GHG) emissions, "[e]missions associated with heavy-duty trucks involved in goods movements are generally controlled on the technology side and through fleet turnover of older trucks and engines to newer and cleaner trucks and engines." The following State strategies reduce GHG emissions from medium and heavy-duty trucks:

- California Air Resources Board (ARB) Mobile Source Strategy focuses on reducing GHGs by transitioning to zero and low emission vehicles and from medium- duty and heavy-duty trucks. ARB's Sustainable Freight Action Plan establishes a goal to improve freight efficiency by 25 percent by 2030, deploy over 100,000 freight vehicles and equipment capable of zero-emission operation and maximize both zero and near-zero-emission freight vehicles and equipment powered by renewable energy by 2030.
- ARB's Truck and Bus Regulation requires diesel-fueled trucks and buses that operate in California to be upgraded to reduce emissions. Newer heavier trucks and buses were required to meet particulate matter (PM) filter requirements beginning January 1, 2012. Lighter and older heavier trucks had a compliance date of January 1, 2015. By January 1, 2023, nearly all trucks and buses will need to have 2010 model year engines or equivalent.
- ARB's Emissions Reduction Plan for Ports and Goods Movement (Goods Movement Plan) in California focuses on reducing heavy-duty truck-related emissions and the establishment of emissions standards for trucks, fleet turnover, truck retrofits, and restriction on truck idling. While the focus of the Goods Movement Plan is to reduce criteria air pollutant and air toxic emissions, the strategies to reduce these pollutants would also generally have a beneficial effect in reducing GHG emissions.

Trucks and truck fleet owners and operators accessing the proposed project would be subject to the above trucking and freight regulations. Thus, these strategies would contribute to controlling heavy-duty truck GHG emissions associated with the proposed project, and the proposed project would not conflict with or inhibit these Statewide strategies." (Draft EIR, page 3.6-57, footnotes omitted.)

In sum, not only do local governments have little or no control over interstate trucking operations, but GHG emissions (and thus VMT as a source of such emissions) resulting from medium- and heavy-

duty truck trips are being addressed separately from GHG emissions (and thus VMT as a source of such emissions) from cars and light trucks. For these reasons, the transportation VMT analysis contained in the Draft EIR met applicable legal standards despite not accounting for medium- and heavy-duty truck trips that, if the proposed project is approved, will result from project operations as a logistics facility.

Even so, however, a recent technical study performed by a leading transportation consultant has found that the significance conclusions in the VMT analysis would not have changed if the analysis were expanded to account for medium- and heavy-duty trucks engaged in logistic operations. The conclusion would still be that VMT-related impacts are less than significant.

Appendix J to the Final EIR is a June 16, 2022, technical memorandum prepared for Joe Livaich of Buzz Oates Construction from Kevin Johnson and David Robinson of Fehr & Peers, a leading transportation consultant, on the subject of "American Canyon Industrial Warehouse Travel Behavior Data." According to its authors, "[a] primary objective of the analysis in this memorandum is to address whether VMT from such heavy-duty truck trips would be more or less than 15 percent below the regional average for the Bay Area." The authors conservatively chose to look at this particular metric because, as noted earlier, the OPR Technical Advisory proposed a significance threshold of 15 percent below the regional average for office projects (although, for reasons discussed above, that threshold was not used in the Draft EIR). The threshold of 15 percent below the regional average was thus the most conservative threshold recommended by OPR, and more conservative than the one used in the Draft EIR.

The Fehr & Peers technical memorandum "describes the travel behavior data collected for the proposed 208-acre high-cube industrial warehouse project (the Project) in American Canyon, CA. Fehr & Peers understands the uniqueness of warehousing and logistics facilities that make them extremely difficult to study with traditional data collection methods. Fehr & Peers combined traffic count data previously collected in San Joaquin County for similar warehousing uses with new mobile device origin-destination data from StreetLight for similar industrial warehouse sites around the Bay Area to provide Buzz Oates Construction, Inc. with detailed trip generation, vehicle origin-destination pattern, and average trip length data." (Fehr & Peers, page 1.)

"This data collection effort was undertaken by Fehr & Peers in June 2021 to better understand the travel behavior of existing warehousing buildings across San Joaquin County, as a review of local and regional planning studies revealed a lack of data and understanding of the travel characteristics of these types of facilities. Specifically, there was a lack of local or national trip generation data for warehousing uses, a lack of understanding of the travel patterns and demographics of warehouse users, and a lack of inclusion of these facilities in regional travel forecasting models." (Fehr & Peers, page 2.)

Fehr & Peers coordinated the collection of 72 hours of driveway vehicle classification count data at 39 warehousing buildings across San Joaquin County in June 2021. The data collection was performed by National Data and Surveying Services (NDS) using cameras to count and classify vehicles entering and exiting the individual building driveways. Fehr & Peers staff visited each of the 39 warehousing buildings on one day during the data collection to observe the following:

- Check traffic and weather conditions
- Confirm the placement of the cameras
- Observe activity levels at the surveyed buildings
- Count the number of truck bays
- Classify the buildings
- Observe general operations and travel behavior

Fehr & Peers used this data to develop average trip generation rates per thousand square feet (KSF) for warehousing uses in San Joaquin County." (Fehr & Peers, page 2.)

Fehr & Peers obtained StreetLight's GPS-based commercial vehicle data product for 23 existing industrial warehousing sites around the Bay Area, including eight sites in Napa County, of which four were located within the City of American Canyon. Fehr & Peers relied on StreetLight's "O-D to Pre-set Geography" product to analyze travel patterns to and from the land use zone system at the census block group level, which has over 23,000 zones within California.

A land use zone system was developed for the 23 existing industrial warehousing sites, each of which included a separate zone for each of the existing buildings or groupings of buildings. The analysis tracked all heavy-duty truck trips starting or ending at one of these zones. The start of trips coming to the zones and end of trips leaving the zones were tagged to the national census block group system, allowing for aggregation to any desired geography such as the city or county level.

The land use zone system consisted of eight industrial warehousing sites in Napa County, which are listed below, and include similar existing warehousing sites in full operation during the data collection period. These sites were selected to understand the potential average trip length of heavy-duty truck trips generated by the proposed project.

The "key findings" of the Fehr & Peers study, summarized on page 12, were as follows:

- The average daily trip generation per KSF of warehousing building space is 0.078 medium-duty truck trips, 0.447 heavy-duty truck trips, 0.995 auto trips, and 1.52 total vehicle trips.
- The average trip length of heavy-duty truck trips generated by the eight existing Napa County industrial warehousing sites in full operation during the data collection period is 35.6 miles.
- The average trip length of heavy-duty truck trips generated by the eight existing Napa County industrial warehousing sites is roughly 39 percent lower than the average trip length for all 23 Bay Area warehousing sites combined.

In short, if the Draft EIR had taken account of medium- and heavy-duty truck trips from logistics operations, as GSEJA suggested was necessary, the analysis would still have concluded that the proposed project would have less than significant VMT-related impacts.

This conclusion is also relevant to the analysis of GHG emissions for the proposed project, which employed a significance threshold very similar to one adopted relatively recently by the Bay Area Air Quality Management District (BAAQMD), by which one factor indicating a less than significant

operational GHG impact was VMT 15 percent below the existing VMT per employee in the Bay Area Region. (Draft EIR, pages 3.6-45 and 3.6-56.) As the preceding discussion indicates, the VMT per employee for the proposed project is roughly 30 percent below the regional average. If medium- and heavy-duty truck traffic from project operations is added to the discussion, the VMT from such traffic is roughly 39 percent below the regional average. Thus, the Fehr & Peers study reinforces and fortifies the Draft EIR's conclusion that operational GHG impacts are less than significant (Draft EIR, page 3.6-59), just as it reinforces and fortifies the Draft EIR's conclusion that VMT-related impacts are less than significant.

SECTION 3: RESPONSES TO WRITTEN COMMENTS

3.1 - List of Authors

A list of public agencies, organizations, and individuals that provided comments on the Giovannoni Logistics Center Project Draft EIR is presented below. Each comment has been assigned a code. Individual comments within each communication have been numbered so comments can be crossed-referenced with responses. Following this list, the text of the communication is reprinted and followed by the corresponding response.

3.2 - Responses to Comments

3.2.1 - Introduction

In accordance with the California Environmental Quality Act (CEQA) Guidelines Section 15088, the City of American Canyon, as the lead agency, evaluated the comments received on the Draft EIR (State Clearinghouse No. 2021010104) for the proposed Giovannoni Logistics Center Project (proposed project), and has prepared the following responses to the comments received. This Response to Comments document becomes part of the Final EIR for the proposed project in accordance with CEQA Guidelines Section 15132.

Comments on an EIR should focus on the sufficiency of the document's identification and analysis of significant environmental impacts, and the adequacy of measures designed to avoid or mitigate those impacts (CEQA Guidelines § 15204(a)). Reviewers should explain the basis for their comments

[1] Includes comments from SWAPE (SWAPE)
[2] Includes comments from Clark & Associates (CLARK), Shannon & Wilson (S&W), Scott Cashen (CASHEN) and Smart Mobility (SM)

and provide data, references, or other evidence to support their comments (CEQA Guidelines § 15204(c)).

CEQA requires that the Final Environmental Impact Report (Final EIR) address comments submitted during the public comment period that raise significant environmental issues (Public Resources Code [PRC] § 21091(d)(2)(B)). The lead agency's written responses shall describe the disposition of such significant environmental issues (e.g., revisions to the proposed project to mitigate anticipated impacts or objections) CEQA Guidelines § 15088(c)).

CEQA does not require that the lead agency respond to every comment submitted to it. While conclusory statements by the lead agency unsupported by factual information will not suffice, the level of detail in the response may correspond to the level of detail in the comment. A general response may be appropriate when a comment does not contain or specifically refer to readily available information or does not explain the relevance of evidence submitted with the comment (CEQA Guidelines § 15088(c)). Additionally, the lead agency generally has considerable leeway regarding responses to comments and need not respond to comments that do not raise a significant environmental issue. The lead agency also need not respond to general reference materials submitted in support of comments, comments that repeat those already considered, or comments that are clearly irrelevant, and the lead agency has the discretion to reject comments that are not focused as provided by the CEQA Guidelines (CEQA Guidelines § 15204(e)).

Pursuant to CEQA Guidelines, personal opinions expressing general support for, or opposition to, the proposed project are noted and will be noted in the response to comments and included within the administrative record for the proposed project, but do not require a specific written response if they do not relate to a significant environmental issue that is addressed within the Draft EIR and/or otherwise within the purview of CEQA. Likewise, opinions about the general desirability, merits, and/or purely economic, social, or political considerations of the proposed project are not within the purview of CEQA and do not require a specific written response in this Final EIR. In cases where the comment provides background information, an opinion and/or generalized concerns about the merits of the proposed project but does not challenge the sufficiency of the Draft EIR, the City will note the comment in these responses and include the opinion in this Final EIR for informational purposes. Where a commenter offers unsubstantiated assertions about a significant environmental issue or the adequacy of the Draft EIR, the City will note the assertion in these responses and include the comment in the Final EIR for informational purposes but will not alter or augment the analysis in the Draft EIR, pursuant CEQA Guidelines Section 15204. Although CEQA does not require a detailed response to each of these general comments in this Final EIR, each comment is part of the administrative record on the proposed project and will be forwarded to City decision-makers for consideration.

3.2.2 - Comment Letters and Responses

The comment letters reproduced in the following pages follow the same organization as used in the List of Authors.

CEQA REVIEW COMMENT SHEET

USDA-Rural Development Environmental Assessment

Giovannoni Logistics Center Project

LDR GTS # 04-NAP-2021-00280

PROJECT LIMITS: 04-NAP-029 PM 3.05

REVIEWED BY: Wichai Hanittinan (510)-286-6431

Office of Highway Operations June 17, 2022

For: Yunshen Luo

Comments:

1) Suggest being specific on a period of time for the VMT mentioned in this report. Is the VMT reported for one year, one month, or one day? 1

2) In Appendix H Transportation Supporting Information, suggest clarifying the following sentence: "The morning peak hour occurs between 7:00 and 9:00 a.m. and reflects conditions during the home to work or school commute, while the p.m. peak hour occurs between 4:00 and 6:00 p.m. and typically reflects the highest level of congestion during the homeward bound commute." 2

   According to its Appendix B Traffic Count Data, the peak hour at each intersection varies, especially during the AM peak period, suggest explain/describe this information in the report.

3) For the traffic count results at the Devlin Rd and S Kelly Rd intersection (intersection 2 as referred in the report) in Appendix B Traffic Count Data of Appendix H Transportation Supporting Information, why are the truck volumes more than the total traffic volumes for the same movement?

   Are the truck volumes reported separately from the traffic volumes for regular vehicles? If this is the case, there are additional 36 trucks on NB Devlin Rd marking the left turn to EB S Kelly Rd during the 8-9 AM peak hour, why are they not accounted/included in the left turn traffic volumes from NB Devlin Rd to EB S Kelly Rd reported in Exhibit 3.12-4 Existing Plus Project Traffic Volumes in the Transportation section of the Draft EIR and Figure 6 – Existing Plus Project Traffic Volumes of Appendix H Transportation Supporting Information? 3

   The same question can also be applied to the 11 trucks on NB Devlin Rd marking the left turn to EB S Kelly Rd during the 4-5 PM peak hour.

4) In Exhibit 3.12-3 Project Traffic Volumes in the Transportation section of the Draft EIR and in Figure 5 – Project Traffic Volumes of Appendix H Transportation Supporting 4

Information, are the traffic volumes reported here additionally generated and reported separately as the results of the project?

And what year of these Project traffic volumes are for, are they for the existing year (2019) or the future year (2040)? 4 CONT

5) If the traffic volumes show in Exhibit 3.12-3 Project Traffic Volumes in the Transportation section of the Draft EIR and in Figure 5 – Project Traffic Volumes of Appendix H Transportation Supporting Information are for the future year (2040), please verify the 2458 (veh) traffic volumes for the northbound through traffic on SR 29. Should it be 2464 (veh) traffic volumes? 5

6) In Exhibit 3.12-3 Project Traffic Volumes in the Transportation section of the Draft EIR and in Figure 5 – Project Traffic Volumes of Appendix H Transportation Supporting Information,

6.1) Why isn't there any EB traffic on Green Island Rd making a left turn to the NB of the future Devlin Rd? Will the intersection between Green Island Rd and the future Devlin Rd prohibit the left-turn movement from the EB Green Island Rd to the NB of the future Devlin Rd? If that is the case, please document and specify it in the report. 6

6.2) Why isn't there any SB traffic on the future Devlin Rd making a right turn to the WB of Green Island Rd . Will the intersection between Green Island Rd and the future Devlin Rd prohibit the right-turn movement from the SB of the future Devlin Rd to the WB Green Island Rd? If that is the case, please document and specify it in the report.

7) For Exhibit 3.12-4 Existing Plus Project Traffic Volumes in the Transportation section of the Draft EIR and Figure 6 – Existing Plus Project Traffic Volumes of Appendix H Transportation Supporting Information,

If these added-on traffic volumes as the results of the project are for the future year (2040), why are they directly added to the traffic volumes for the existing year (2019) to obtain the results for Existing Plus Project Traffic Volumes as shown in the Exhibit 3.12-4 and Figure 6 mentioned above? 7

8) In Exhibit 3.12-5 Future Traffic Volumes in the Transportation section of the Draft EIR and in Figure 3 – Future Traffic Volumes of Appendix H Transportation Supporting Information, are these future traffic volumes for the future year (2040) under the existing conditions without the project? 8

9) For Exhibit 3.12-6 Future Plus Project Traffic Volumes in the Transportation section of the Draft EIR and Figure 7 – Future Plus Project Traffic Volumes of Appendix H Transportation Supporting Information,

If these added-on traffic volumes as the results of the project are for the existing year (2019), why are they directly added to the traffic volumes for the future year (2040) to obtain the results for Future Plus Project Traffic Volumes as shown in the Exhibit 3.12-4 and Figure 6 mentioned above? Are they expected to increase in the future year (2040) to get the traffic volumes for the Future Plus Project Traffic Volumes? 9

10) Since the traffic data presented in Appendix B Traffic Count Data of Appendix H Transportation Supporting Information were collected from a few samples, suggest also 10

presenting and discussing/comparing with the historical traffic data and census, such as those obtained by Caltrans or from other sources.

For an example, the traffic volumes for the Ahead Peak Hour and Back Peak Hour at NAP 29 PM 3.601 (at the S Kelly Rd and SR-29 intersection) were 3,700 and 3,100 respectively. In addition, the average historical traffic volumes during the AM and PM peak hour(s) in weekdays at nearby SR-29 PM 3.601 can be obtained and compared with the traffic data presented in this report.

10
CONT

THIS PAGE INTENTIONALLY LEFT BLANK

State Agencies

California Department of Transportation (CALTRANS)

Response to CALTRANS-1
The agency inquired about the time period for the Vehicle Miles Traveled (VMT) analysis (e.g., one year, one month, or one day?).

As described on page 20 of the Traffic Impact Study for the Giovannoni Logistics Center (Appendix H, Transportation Supporting Information), the VMT reported is measured in VMT per capita, or the number of daily miles driven per employee. See also Master Response 4—Vehicle Miles Traveled.

Response to CALTRANS-2
The agency requested a clarification about the description of the AM and PM peak-hours and suggested that an explanation be provided about the variation in the peak-hour at each study intersection.

The peak-hour varies from intersection to intersection, and all were evaluated based on the highest-volume hour at that location to provide a conservative analysis.

Response to CALTRANS-3
The agency inquired about discrepancies in the traffic volumes for various turn movements at Devlin Road/South Kelly Road shown on Draft EIR Section 3.12, Transportation Exhibit 3.12-4.

The reported truck values in Appendix B Traffic Count Data of Draft EIR Appendix H summarize the percentage of vehicles that are trucks at each turning movement, and do not report the number (or volume) which are trucks.

Response to CALTRANS-4
The agency inquired whether the traffic volumes shown on Draft EIR Exhibit 3.12-3 are additionally generated or reported separately. The agency inquired about the year the volumes shown on Draft EIR Exhibit 3.12-3.

The number of newly-generated vehicle trips is summarized in Draft EIR Exhibit 3.12-3. The number of trips does not change between the existing and future conditions. Therefore, these project-generated trips are applicable to both the Existing Plus Project and Future Plus Project conditions evaluated.

Response to CALTRANS-5
The agency requested clarification about the northbound through volumes on State Route (SR) 29 shown in Draft EIR Exhibit 3.12-3.

The value of 2,458 shown at Intersection No. 1 on Draft EIR Exhibit 3.12-6 is correct. However, the value 2,458 shown at Intersection No. 1 on Draft EIR Exhibit 3.12-5 is a typo and should be 2,451 instead. The proposed project is expected to add seven vehicles to the existing 2,451 trips without the proposed project, resulting in a volume of 2,458 when project trips are added (as depicted on Draft EIR Exhibit 3.12-6). The analysis was based on the correct number and is unaffected by this typo. The corrected Draft EIR Exhibit 3.12-5 is provided in Final EIR Section 5, Errata.

Response to CALTRANS-6
The agency inquired about the traffic volumes at Green Island Road/Devlin Road shown in Draft EIR Exhibit 3.12-3 and requested clarification about various turn movements.

The trip distribution, summarized on Table 7 (Appendix H Transportation Supporting Information), shows all project-related traffic would solely use SR-29 to access the project site. This means there are assumed to be no trips heading to or arriving from Green Island Road west of the project site, as this route does not have a direct connection with SR-29.

Turn prohibitions are not proposed at the future intersection of Devlin Road/Green Island Road.

Response to CALTRANS-7
The agency inquired about the volumes shown in Draft EIR Exhibit 3.12-4.

The number of new trips attributable to the proposed project is constant and not anticipated to change from year to year. Therefore, the proposed project is expected to contribute the same number of vehicle trips to the roadway network during both the existing and future years.

Response to CALTRANS-8
The agency requested clarification about the traffic volumes shown on Draft EIR Exhibit 3.12-5.

As described on pages 9 through 11 of Appendix H, Transportation Supporting Information, the volumes shown in Figure 3 represent the anticipated volumes for the year 2040 without the proposed project.

Response to CALTRANS-9
The agency requested clarification about traffic volumes shown on Draft EIR Exhibit 3.12-6.

Refer to Response to CALTRANS-4 and Response to CALTRANS-7.

Response to CALTRANS-10
The agency requested the traffic volumes provided in Appendix H on SR-29 at Post Mile 3.601 be compared to historical traffic data and census.

Traffic volumes provided in Appendix H were based on actual counts taken at the study intersections. Comparing traffic volumes in Appendix H to historical traffic data along SR-29 would not provide further insight into assessing traffic effects attributable to the proposed project.

Subject: Giovannoni Logistics Center Project, Draft Environmental Impact Report, SCH No. 2021010104, City of American Canyon, Napa County

Dear Mr. Cooper:

The California Department of Fish and Wildlife (CDFW) received a Notice of Availability of a draft Environmental Impact Report (DEIR) from the City of American Canyon (City) for the Giovannoni Logistics Center Project (Project) pursuant the California Environmental Quality Act (CEQA) and CEQA Guidelines.[1] CDFW previously submitted comments in response to the Notice of Preparation of the DEIR.

CDFW is submitting comments on the DEIR to inform the City, as the Lead Agency, of potentially significant impacts to biological resources associated with the Project.

CDFW ROLE 1

CDFW is a **Trustee Agency** with responsibility under CEQA pursuant to CEQA Guidelines section 15386 for commenting on projects that could impact fish, plant, and wildlife resources. CDFW is also considered a **Responsible Agency** if a project would require discretionary approval, such as permits issued under the California Endangered Species Act (CESA), the Lake and Streambed Alteration Program, or other provisions of the Fish and Game Code that afford protection to the state's fish and wildlife trust resources.

PROJECT DESCRIPTION SUMMARY

Proponent: Buzz Oates

Objective: Develop a 2.4-million square-foot logistics center on an approximately 208-acre site; 163 acres would be developed, and 45 acres would be preserved as wetlands. In conjunction with the Project, the City would extend Devlin Road through the 2

[1] CEQA is codified in the California Public Resources Code in section 21000 et seq. The "CEQA Guidelines" are found in Title 14 of the California Code of Regulations, commencing with section 15000.

DocuSign Envelope ID: A59D3452-8C9D-4684-8C9C-56BA7F98131A

Project site. The Project is proposed to occur in two phases. During Phase 1, the 94.7-acre area east of the Devlin Road extension would be developed. During Phase 2, the 113.1-acre area west of Devlin Road would be developed.

Location: The Project site is in the City of American Canyon, approximately one mile southeast of the Napa County Airport and directly west of State Route 29, in southern Napa County. The Project site is bounded by the Napa Logistics Park and Devlin Road to the north and Green Island Business Park (i.e., industrial development) to the southwest, and centered at approximately Latitude 38.198921°N, Longitude 122.268598°W. 2

REGULATORY REQUIREMENTS

California Endangered Species Act

Please be advised that a CESA Incidental Take Permit (ITP) must be obtained if the Project has the potential to result in "take" of plants or animals listed under CESA, either during construction or over the life of the Project**. The Project has the potential to impact Swainson's hawk (*Buteo swainsoni*) and tricolored blackbird (*Agelaius tricolor*), both of which are CESA listed as threatened species, as further described below.** Issuance of an ITP is subject to CEQA documentation; the CEQA document must specify impacts, mitigation measures, and a mitigation monitoring and reporting program. If the Project will impact CESA listed species, early consultation is encouraged, as significant modification to the Project and mitigation measures may be required in order to obtain an ITP.

CEQA requires a Mandatory Finding of Significance if a project is likely to substantially restrict the range or reduce the population of a threatened or endangered species. (Pub. Resources Code, §§ 21001, subd. (c) & 21083; CEQA Guidelines, §§ 15380, 15064, & 15065). Impacts must be avoided or mitigated to less-than-significant levels unless the CEQA Lead Agency makes and supports Findings of Overriding Consideration (FOC). The CEQA Lead Agency's FOC does not eliminate the project proponent's obligation to comply with CESA. 3

Fully Protected Species

Fully Protected species, such as golden eagle (*Aquila chrysaetos*), may not be taken or possessed at any time (Fish & G. Code, §§ 3511, 4700, 5050, & 5515) except for collecting these species for necessary scientific research, relocation of the bird species for the protection of livestock, or if they are a covered species whose conservation and management is provided for in a Natural Community Conservation Plan.

DocuSign Envelope ID: A59D3452-8C9D-4684-8C9C-56BA7F98131A

COMMENTS AND RECOMMENDATIONS

CDFW offers the comments and recommendations below to assist the City in adequately identifying and/or mitigating the Project's significant, or potentially significant, direct and indirect impacts on fish and wildlife (biological) resources. Editorial comments or other suggestions may also be included to improve the document. Based on the potential for the Project to have a significant impact on biological resources, CDFW concludes that an environmental impact report is appropriate for the Project. 4

Mandatory Findings of Significance: Does the Project have the potential to substantially reduce the number or restrict the range of an endangered, rare, or threatened species?

Environmental Setting and Mitigation Measures

COMMENT 1: Swainson's Hawk MM BIO-1a (Section 3.3, Pages 24-27)

Issue: Mitigation measure (MM) BIO-1a identifies a 1,000-foot no disturbance buffer shall be established for any Swainson's hawk nest, which may be insufficient to reduce impacts to Swainson's hawk to less-than-significant and comply with CESA. 5a

Furthermore, the language of MM BIO-1a regarding when surveys will occur should be revised for clarity to ensure any nesting Swainson's hawks that could be disturbed by the Project are detected. In the first paragraph it states that surveys will be completed for at least two survey periods prior to commencement of construction. In the second paragraph it inconsistently states that construction may commence if no nesting Swainson's hawks are found during the first non-optional survey period.

Additionally, the DEIR identifies the Project will remove Swainson's hawk foraging habitat, but it does not specify the number of acres that the Project will remove. Therefore, the approximately 45 acres of wetlands that will be preserved by the Project may not be sufficient to mitigate for the loss of Swainson's hawk foraging habitat. 5b Additionally, please note that the presence of suitable Swainson's hawk foraging habitat near the Project site does not negate the need to mitigate for the permanent removal of foraging habitat for this species.

Specific impacts and why they may occur and be significant: If active Swainson's hawk nests are not detected by the proposed surveys or appropriate buffer zones are not established, Swainson's hawks could be disturbed by Project activities resulting in nest abandonment and loss of eggs or reduced health and vigor and loss of young, thereby substantially reducing the number of the species. 5c Additionally, loss of foraging habitat is the primary threat to Swainson's hawk populations in California (CDFW 2016). Swainson's hawk is CESA listed as a threatened species and therefore is considered to be a threatened species pursuant to CEQA Guidelines section 15380. Therefore, if an

DocuSign Envelope ID: A59D3452-8C9D-4684-8C9C-56BA7F98131A

active Swainson's hawk nest is disturbed by the Project, the Project may result in a substantial reduction in the number of a threatened species, which is considered a Mandatory Finding of Significance pursuant to CEQA Guidelines section 15065, subdivision (a)(1). 5c

Recommendation: For an adequate environmental setting, to reduce impacts to Swainson's hawk to less-than-significant, and to comply with CESA, CDFW recommends revising MM BIO-1a to require that Swainson's hawk surveys be conducted by a qualified biologist with experience surveying for and detecting the species pursuant to the *Recommended timing and methodology for Swainson's Hawk Nesting Surveys in California's Central Valley Swainson's Hawk* (2000) survey protocol, within 0.5 mile of the Project site each year that Project activities occur. Pursuant to the above survey protocol, surveys shall be completed for at least the two survey periods immediately prior to a Project's initiation. For example, if the project is scheduled to begin on June 20, the qualified biologist shall complete three surveys in Period III and three surveys in Period V. It is recommended that surveys be completed in Periods II, III and V. Surveys in Period I may be required if the Project will commence by April 5. The Project shall obtain CDFW's written acceptance of the qualified biologist and survey report prior to Project construction occurring between March 1 and August 31 each year. If the qualified biologist identifies nesting Swainson's hawks, the Project shall implement a 0.5 mile no disturbance buffer zone around the nest, unless otherwise approved in writing by CDFW. Project activities shall be prohibited within the buffer zone between March 1 and August 31, unless otherwise approved in writing by CDFW. If take of Swainson's hawk cannot be avoided, the Project shall consult with CDFW pursuant to CESA and obtain an ITP. 5d

Additionally, to mitigate for the loss of foraging habitat, CDFW recommends including a mitigation measure that requires the preservation through a conservation easement of Swainson's hawk foraging habitat, of equal or greater habitat value than that which will be impacted by the Project, in perpetuity at a minimum 1:1 mitigation to impact ratio. CDFW must provide written approval of the habitat proposed for preservation prior to the start of Project activities. 5e

COMMENT 2: Tricolored Blackbird (Section 3.3, Page 26)

Issue: The DEIR identifies there will be no impact on tricolored blackbird because there is no suitable nesting habitat within the Project site. However, the Project may impact tricolored blackbird that occur within 500 feet of the Project site. 6a

Specific impacts and why they may occur and be significant: If active tricolored blackbird nests are not detected by the proposed surveys or appropriate buffer zones are not established, tricolored blackbird could be disturbed by Project activities resulting in nest abandonment and loss of eggs or reduced health and vigor and loss of young,

DocuSign Envelope ID: A59D3452-8C9D-4684-8C9C-56BA7F98131A

thereby substantially reducing the number of the species. Tricolored blackbird is CESA listed as a threatened species and therefore is considered to be a threatened species pursuant to CEQA Guidelines section 15380. Therefore, if an active tricolored blackbird nest is disturbed by the Project, the Project may result in a substantial reduction in the number of a threatened species, which is considered a Mandatory Finding of Significance pursuant to CEQA Guidelines section 15065, subdivision (a)(1). 6a

Recommendation: For an adequate environmental setting, to reduce impacts to tricolored blackbird to less-than-significant, and to comply with CESA, CDFW recommends revising MM BIO-4 to require that a survey for active tricolored blackbird nests shall be conducted by a qualified biologist within seven days prior to the beginning of Project activities, and within a minimum 500-foot distance of the Project. If nesting bird surveys, per MM BIO-4, detect nesting tricolored blackbird or evidence of their presence, CDFW shall be notified immediately, and Project activities shall not occur without written approval from CDFW allowing the Project to proceed. Presence of nesting tricolored blackbird may require CESA consultation and an Incidental Take Permit before Project activities may commence. If a lapse in Project construction of seven days or more occurs during nesting season, another survey shall be conducted. Please note, this also addresses impacts to nesting birds, which are protected under Fish and Game Code sections 3503, 3503.5, and 3513. Migratory birds are also protected under the federal Migratory Bird Treaty Act. 6b

Would the Project have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by CDFW or U.S. Fish and Wildlife Service?

Mitigation Measures

COMMENT 3: Golden Eagle MM-BIO 1b (Section 3.3, Pages 27)

Issue: MM-BIO 1b identifies a 1,000-foot no disturbance buffer shall be established for any golden eagle nests within 1,000 feet of construction activities, which may be insufficient to reduce impacts to golden eagle to less-than-significant. Additionally, the measure allows for modification of the buffer zone depending on behavioral factors and acclimation of nesting golden eagles. CDFW should be consulted before implementation of a reduced buffer zone to ensure protection of any nesting golden eagle. 7a

Specific impacts and why they may occur and be significant: Golden eagle is a fully protected species and may not be taken or possessed at any time, except as described above (Fish & G. Code, §§ 3511), and is also protected under the federal Bald and Golden Eagle Protection Act. Golden eagle is highly sensitive to human disturbance which can result in lower brood size (Steenhof et al. 2014), lower nest

DocuSign Envelope ID: A59D3452-8C9D-4684-8C9C-56BA7F98131A

attendance (Spaul and Heath 2016), and increased time spent away from the nest (Spaul and Heath 2017). If appropriate buffer zones are not established around active golden eagle nests, Project impacts to golden eagle would be potentially significant. 7a

Recommendation: For an adequate environmental setting and to reduce impacts to golden eagle to less-than-significant, CDFW recommends revising MM BIO-1b to require that the survey area for golden eagle shall be determined by a qualified Raptor Biologist in consultation with CDFW, and if any golden eagle nest is identified during pre-construction golden eagle nesting surveys, a biological based justification for the buffer zone, as determined by a qualified Raptor Biologist, shall be submitted to CDFW for review. Project activities shall not proceed between March 1 and August 31 unless CDFW provides written approval of the buffer zone around any golden eagle nest. 7b

COMMENT 4: Northern Harrier MM-BIO 1c (Section 3.3, Pages 27)

Issue: It appears that surveys for nesting northern harrier (*Circus hudsonius*) would only occur within the Project site. However, nesting northern harrier may be impacted if they occur off-site within a minimum 500-foot radius around the Project site.

Additionally, MM-BIO 1c allows for modification of the buffer zone depending on behavioral factors and acclimation of northern harrier. CDFW should be consulted before implementation of a reduced buffer zone.

Specific impact and why they may occur and be significant: If an active northern harrier nest is present within a minimum of 500 feet of the Project and is not detected by the proposed surveys, or appropriate no disturbance buffer zones are not implemented, nesting northern harriers could be disturbed by Project activities resulting in nest abandonment and loss of eggs or reduced health and vigor and loss of young. Northern harrier is a California Species of Special Concern (SSC). An SSC is a species, subspecies, or distinct population of an animal native to California that currently satisfies one or more of the following (not necessarily mutually exclusive) criteria: is extirpated from the State or, in the case of birds, is extirpated in its primary season or breeding role; is listed as Federally-, but not State-, threatened or endangered; meets the State definition of threatened or endangered but has not formally been listed; is experiencing, or formerly experienced, serious (noncyclical) population declines or range retractions that, if continued or resumed, could qualify it for State threatened or endangered status; or has naturally small populations exhibiting high susceptibility to risk from any factor(s), that if realized, could lead to declines that would qualify it for State threatened or endangered status. Therefore, if nesting northern harriers are present and would be disturbed by the Project, impacts to northern harrier would be potentially significant. 8a

Recommendation: For an adequate environmental setting and to reduce impacts to northern harrier to less-than-significant, CDFW recommends revising MM BIO-1c to 8b

DocuSign Envelope ID: A59D3452-8C9D-4684-8C9C-56BA7F98131A

require submission of a biological based justification for reducing the buffer zone, as determined by the qualified Raptor Biologist, to CDFW for review. Project activities shall not commence until CDFW provides written approval for the reduction of the no disturbance buffer zone around any northern harrier nest.

8b

Additionally, MM BIO-1c should be revised to state that surveys shall be conducted to determine the presence of nesting northern harrier within a minimum 500-foot radius around the Project site.

COMMENT 5: Burrowing Owl MM BIO-1d (Section 3.3, Page 28)

Issue: MM BIO-1d indicates that surveys for burrowing owl (*Athena cunicularia*) would occur within two weeks prior to Project construction and a 100-foot no disturbance buffer would be implemented around refugia occupied by non-nesting wintering owls. However, the aforementioned survey and buffer distance may not be adequate to detect and avoid Project impacts to burrowing owls. The Project may result in the loss of burrowing owl breeding and non-breeding habitat and would likely result in the loss of foraging habitat.

Specific impacts and why they may occur and be significant: The Project could result in burrowing owl nest abandonment, loss of young, reduced health and vigor of owlets, or injury or mortality of adults, and a permanent reduction of burrowing owl habitat in Napa County.

Burrowing owl is an SSC because the species' population viability and survival are adversely affected by risk factors such as precipitous declines from habitat loss, fragmentation, and degradation; evictions from nesting sites without habitat mitigation; wind turbine mortality; human disturbance; and eradication of California ground squirrels (*Spermophilus beecheyi*) resulting in a loss of suitable burrows required by burrowing owls for nesting, protection from predators, and shelter (Shuford and Gardali 2008; CDFW 2012 Staff Report; personal communication, CDFW Statewide Burrowing Owl Coordinator Esther Burkett, May 13, 2022). Preliminary analyses of regional patterns for breeding populations of burrowing owls have detected declines both locally in their central and southern coastal breeding areas, and statewide where the species has experienced breeding range retraction (CDFW 2012 Staff Report; personal communication, Esther Burkett, May 13, 2022).

9a

Historically, the most abundant populations of burrowing owl within the San Francisco Bay Area were in Alameda, Contra Costa, and Santa Clara counties and populations were locally abundant within portions of Solano and San Mateo counties. Burrowing owls are no longer abundant and may be disappearing entirely from western Contra Costa, western Alameda, and Santa Clara counties. Breeding burrowing owls may be extirpated in Marin County, and only use the region on a limited basis in winter

(Townsend and Lenihan 2007 as cited in Sheffield 2021). Habitat loss caused by development is the most immediate threat to burrowing owls in high growth areas of the San Francisco Bay Area, and loss of burrowing owl habitat will likely continue well into the future (Townsend and Lenihan 2007). As urbanization increases and local burrowing owl populations decline, they become vulnerable to stochastic events (demographic, genetic, and environmental) associated with small population size, creating the potential for an extinction "vortex" (Gilpin and Soulé 1986 as cited in Townsend and Lenihan 2007). 9a

Based on the above, if the Project would result in impacts to burrowing owl, Project impacts to burrowing owls would be potentially significant.

Recommendation: For an adequate environmental setting and to reduce impacts to burrowing owl to less-than-significant, CDFW recommends that MM BIO-1d be revised to require that a habitat assessment, and if warranted based on the habitat assessment breeding and non-breeding surveys, be conducted in conformance with the CDFW 2012 Staff Report on Burrowing Owl Mitigation (2012 Staff Report), which states: A) breeding season surveys should include four survey visits: 1) at least one site visit between 15 February and 15 April, and 2) a minimum of three survey visits, at least three weeks apart, between 15 April and 15 July, with at least one visit after 15 June; and B) non-breeding season surveys shall be conducted according to the methods described for breeding season surveys (i.e., a minimum of three survey visits, at least three weeks apart), but conduct at least four visits, spread evenly throughout the non-breeding season. The habitat assessment and surveys shall be conducted within 500 meters (1,640 feet) of the Project site for breeding or non-breeding burrowing owls and the no disturbance buffer distance of 500 meters outlined in the 2012 Staff Report shall be implemented, unless otherwise approved in writing by CDFW. 9b

Additionally, pursuant to the 2012 Staff Report, CDFW does not consider eviction of western burrowing owl (i.e., passive removal of an owl from its burrow or other shelter) as a "take" avoidance, minimization, or mitigation measure. Therefore, to reduce impacts to burrowing owl to less-than-significant, off-site habitat compensation shall be included in the eviction plan. Habitat compensation acreages shall be approved by CDFW, as the amount depends on site-specific conditions, and completed before Project construction. It shall also include placement of a conservation easement and preparation and implementation of a long-term management plan.

If the Project would impact an unoccupied nesting burrowing owl burrow or burrow surrogate (i.e., a burrow known to have been used in the past three years for nesting), or an occupied burrow (where a non-nesting owl would be evicted as described above), the following habitat mitigation shall be implemented prior to Project construction:

Impacts to each nesting site shall be mitigated by permanent preservation of two occupied nesting sites with appropriate foraging habitat within Solano County, unless otherwise approved by CDFW, through a conservation easement and implementing and funding a long-term management plan in perpetuity. The same requirements shall apply for impacts to non-nesting evicted owl sites.

Impacts to burrowing owl foraging habitat shall be mitigated by permanent preservation through a conservation easement of foraging habitat at a 1:1 mitigation to impact ratio, in the same manner described above, and accepted by CDFW in writing. The CDFW 2012 Staff Report states, “current scientific literature supports the conclusion that mitigation for permanent habitat loss necessitates replacement with an equivalent or greater habitat area for breeding, foraging, wintering, dispersal…” 9b

EDITORIAL SUGGESTIONS

Clarify the development footprint for the Project component compared to the Program component. It is unclear if the 208-acre Project site will be used for both Phase 1 and Phase 2, or if a different site will be used for Phase 2. 10

The Project Summary (Section 2.3.1) indicates 163-acres will be developed. However, it also states that the Phase 1 will develop 94.7 acres and Phase 2 will develop 113.1 acres, for a total of approximately 208 acres. If the 208-acre Project site is specific to Phase 1, and only 94.7 acres will be developed during Phase 1, it is unclear what is occurring on the remaining 68.3 acres of the 163 acres planned for development. 11

CDFW recommends providing an aerial image outlining where both Phase 1 and Phase 2 development will occur, as well as the 44.8 acres that will be preserved as open space. 12

ENVIRONMENTAL DATA

CEQA requires that information developed in environmental impact reports and negative declarations be incorporated into a database which may be used to make subsequent or supplemental environmental determinations. (Pub. Resources Code, § 21003, subd. (e)). Accordingly, please report any special-status species and natural communities detected during Project surveys to the California Natural Diversity Database (CNDDB). The CNNDB field survey form can be filled out and submitted online at the following link: https://wildlife.ca.gov/Data/CNDDB/Submitting-Data. The types of information reported to CNDDB can be found at the following link: https://www.wildlife.ca.gov/Data/CNDDB/Plants-and-Animals. 13

ENVIRONMENTAL DOCUMENT FILING FEES

The Project, as proposed, would have an impact on fish and/or wildlife, and assessment of environmental document filing fees is necessary. Fees are payable upon filing of the Notice of Determination by the Lead Agency and serve to help defray the cost of environmental review by CDFW. Payment of the environmental document filing fee is required in order for the underlying project approval to be operative, vested, and final. (Cal. Code Regs, tit. 14, § 753.5; Fish & G. Code, § 711.4; Pub. Resources Code, § 21089). 14

CONCLUSION

CDFW appreciates the opportunity to comment on the DEIR to assist the City in identifying and mitigating Project impacts on biological resources.

Questions regarding this letter or further coordination should be directed to Alicia Bird, Environmental Scientist, at (707) 980-5154 or alicia.bird@wildlife.ca.gov; or Melanie Day, Senior Environmental Scientist (Supervisory), at (707) 210-4415 or melanie.day@wildlife.ca.gov. 15

Sincerely,

California Department of Fish and Wildlife (CDFW)

Response to CDFW-1
The agency provided introductory remarks. No response is necessary.

Response to CDFW-2
The agency summarized the proposed project. No response is necessary.

Response to CDFW-3
The agency noted the proposed project may require an Incidental Take Permit for plants or animals including the Swainson's hawk and tricolored blackbird. The agency also noted CEQA requires a mandatory finding of a significance if a project is likely to substantially restrict the range or reduce the population of a threatened or endangered species.

Mitigation Measure (MM) BIO-1a indicates an Incidental Take Permit shall be required if there is a valid concern the project activities would result in the "take" of an adult Swainson's hawk or nestlings. As such, the Draft EIR disclosed this possibility. No Incidental Take Permit will be necessary solely due to the loss of foraging habitat, as such an outcome does not directly or foreseeably result in the mortality of individual hawks or nestlings.

The Draft EIR included, as a significance threshold, whether the proposed project would substantially reduce the number or restrict the range of an endangered, rare or threatened species. (Draft EIR, page 3.3-22.) Applying this threshold, the Draft EIR found all impacts on special-status species could be mitigated to a level of less than significant. The proposed project, as mitigated, therefore would not substantially reduce or restrict the range or reduce the population of the Swainson's hawk. See also Master Response 1—Impacts to Swainson's Hawk/Golden Eagle Foraging Habitat.

Response to CDFW-4
The agency indicated an EIR is the appropriate level of CEQA documentation for the proposed project.

The City of American Canyon concurs an EIR is the appropriate level of CEQA documentation for the proposed project.

Response to CDFW-5a
The agency stated a 1,000-foot non-disturbance buffer from an active Swainson's hawk nest identified in MM BIO-1a may not be sufficient to reduce impacts to less than significant and comply with the California Endangered Species Act (CESA).

MM BIO-1a identifies a "minimum" 1,000-foot non-disturbance buffer to be established from an active Swainson's hawk nest, and if Swainson's hawk are found to be nesting within 1,000 feet of the project site, MM BIO-1a requires the Biologist to consult with the CDFW regarding the adequacy of the buffer. As explained in the Draft EIR, all Swainson's hawk surveys would be conducted within 0.5 mile of proposed work areas. If the CDFW determines a larger buffer may be warranted to comply with CESA, the buffer may be increased.

The agency also requested the language in MM BIO-1a regarding when surveys would occur should be revised for clarity. The CDFW noted in the first paragraph of MM BIO-1a in the Draft EIR states surveys would be completed for at least two survey periods prior to the commencement of construction but the second paragraph states construction may commence if no nesting Swainson's hawk are found during the first "non-optional" survey period.

The Swainson's Hawk Technical Guidelines state the first survey is "optional." The first "non-optional" survey period stated in the second paragraph of MM BIO-1a is the second survey. Although the language in MM BIO-1a is technically consistent it may not be clear to all readers. In response to CDFWs comment, the first sentence of the second paragraph should be amended for clarity as follows:

> "If no nesting Swainson's hawk are found during the ~~first non-optional~~ second survey period starting March 20, then project construction may commence."

Response to CDFW-5b

The CDFW noted the Draft EIR identifies the proposed project would remove Swainson's hawk foraging habitat but does not specify the acreage.

Swainson's hawk foraging habitat is addressed in Master Response 1.

Response to CDFW-5c

The agency stated if active Swainson's hawk nests are not detected by the proposed surveys, or if appropriate buffer zones are not established, Swainson's hawk could be disturbed by project activities resulting in nest abandonment and loss of eggs or reduced health and vigor and loss of young, thereby substantially reducing the number of Swainson's hawks. The agency also stated the loss of foraging habitat is the primary threat to Swainson's hawk populations in California. The agency concludes that if an active Swainson's hawk nest is disturbed by the proposed project, the proposed project may result in a substantial reduction in the number of a threatened species, which is considered a Mandatory Finding of Significance pursuant to CEQA Guidelines Section 15065, subdivision (a)(1).

The Draft EIR acknowledges in Section 3.3, Biological Resources, page 3.3-24, that if Swainson's hawk was found nesting within a zone of influence (which is generally considered within 1,000 feet) during the construction period, potential impacts to this species could occur, including disturbance to nesting birds and possible mortality of adults and/or young. Draft EIR Section 3.3, Biological Resources, page 3.3-26 also acknowledges the level of impact to a nesting Swainson's hawk is potentially significant. To avoid impacting an active Swainson's hawk nest, MM BIO-1a requires implementing pre-construction surveys for Swainson's hawk following CDFW guidelines for conducting surveys for Swainson's hawk were developed by the Swainson's Hawk Technical Advisory Committee specifically to maximize locating nesting Swainson's hawk and reduce nest failures due to project activities and/or disturbances. These pre-construction surveys would be conducted at all locations within 0.5 mile of work areas. Implementation of MM BIO-1a would reduce potential impacts to this impact to less than significant and ensure the proposed project would not result in a substantial reduction in the number of this threatened species.

Refer to Master Response 1 for discussion of Swainson's hawk foraging habitat.

Response to CDFW-5d
To reduce impacts to Swainson's hawk to less than significant and comply with CESA, CDFW recommends revising MM BIO-1a to require a Swainson's hawk survey be conducted by a qualified Biologist with experience surveying for and detecting the species pursuant to the *Recommended Timing and Methodology for Swainson's Hawk Nesting Surveys in California's Central Valley* survey protocol within 0.5 mile of the project site each year proposed project activities occur.

Conducting surveys each year project activities occur is not warranted when construction is continuous. As stated in Draft EIR MM BIO-1a, if Swainson's hawk are found nesting in the project vicinity and construction has commenced, it shall be assumed the Swainson's hawk commenced nesting and thus the Swainson's hawk are habituated to the ambient level of noise and disturbance emanating from the project site.

If project activities have commenced, but are delayed prior to the second survey period (March 20 to April 5), and scheduled to recommence during the second survey period but before August 1, then surveys should be repeated to avoid impacting nesting Swainson's hawk that may have started nesting during this period of delayed construction.

In response to CDFWs comment, the MM BIO-1a shall be revised to include additional survey language if construction is delayed and minimum requirements for the qualified Raptor Biologist. MM BIO-1a shall be revised as follows:

> Pre-construction surveys for Swainson's hawk shall be conducted in the project site vicinity prior to initiation of project construction activities, and each year following initiation of construction if project activities are delayed or discontinued for 7 or more days prior to the second survey period (March 20 to April 5), and are scheduled to recommence construction activities during the second survey period but before August 1. These pre-construction surveys shall include investigation of all potential nesting trees within a half-mile radius around all project activities and shall be completed for at least two survey periods immediately prior to commencement of project construction. Surveys shall be conducted in accordance with the California Department of Fish and Wildlife (CDFW) *Recommended Timing and Methodology for Swainson's Hawk Nesting Surveys in California's Central Valley* ~~follow California Department of Fish and Wildlife (CDFW) guidelines for conducting surveys for Swainson's hawk that were developed by the Swainson's Hawk Technical Advisory Committee~~ to maximize the potential for locating nesting Swainson's hawk and reduce the potential for nest failures due to project activities and/or disturbances.
>
> If no nesting Swainson's hawk are found during the ~~first non-optional~~ second survey period starting March 20, then project construction may commence. If during the third surveys (April 5–April 20) Swainson's hawk are found to be nesting in the project vicinity and construction has commenced, it shall be assumed the Swainson's

hawk commenced nesting and thus the Swainson's hawk are habituated to the ambient level of noise and disturbance emanating from the project site.

If Swainson's hawk are found to be nesting within 1,000 feet of the project site, a non-disturbance buffer shall be established to keep all construction activities a minimum of 1,000 feet from the nest site. The CDFW shall be consulted regarding the adequacy of the buffer established by the qualified Raptor Biologist. At that time the necessity for acquiring a Fish and Game Section 2081 Incidental Take Permit (ITP) authorization would be determined. An ITP authorization shall be required if there were a valid concern the project activities would result in the "take" of an adult Swainson's hawk, eggs, or nestlings.

Surveys shall be conducted by a qualified Raptor Biologist with at least 2 years of experience surveying for and detecting Swainson's hawk pursuant to the *Recommended Timing and Methodology for Swainson's Hawk Nesting Surveys in California's Central Valley* survey protocol. No disturbance such as construction or earthmoving activity shall occur within the established buffer zone until it is determined by a qualified Raptor Biologist the young have fledged or the nesting cycle is complete based on monitoring of the active nest by a qualified Biologist.

The CDFW recommended the project obtain CDFW's written acceptance of the qualified Biologist and survey report prior to the project construction occurring between March 1 and August 31 each year.

Conducting Swainson's hawk surveys and establishing buffers do not require obtaining an Incidental Take Permit or coordination with the CDFW, and coordination with the CDFW is not required to reduce impacts to less than significant. Revisions to MM BIO-1a defining the minimum qualifications of the "qualified Raptor Biologist" would ensure surveys are conducted pursuant to *Recommended Timing and Methodology for Swainson's Hawk Nesting Surveys in California's Central Valley* survey protocol and would ensure potential impacts to active Swainson's hawk are less than significant.

The CDFW also recommended the project implement a 0.5-mile non-disturbance buffer zone around a nest and prohibit work between March 1 and August 31, unless otherwise approved in writing by the CDFW.

Draft EIR Section 3.3, Biological Resources, page 3.3-24 acknowledged if Swainson's hawk was found nesting within a zone of influence (which is generally considered within 1,000 feet) during the construction period, potential impacts to this species could occur, including disturbance to nesting birds and possible mortality of adults and/or young. To avoid impacting an active Swainson's hawk nest, Draft EIR MM BIO-1a requires a non-disturbance buffer be established to keep all construction activities a minimum of 1,000 feet from a Swainson's hawk nest meaning the Biologist could require a larger buffer. In addition, although not required by law, MM BIO-1a additionally requires the CDFW be consulted regarding the adequacy of the buffer established by the qualified Raptor Biologist. If the CDFW determines a larger buffer may be warranted to comply with CESA, the buffer may be increased. Based on the ambient noise and visual disturbance surrounding the project site being

adjacent to large commercial developments, major highway, and residential communities, construction of the proposed project would not be expected to affect a nesting Swainson's hawk 0.5 mile from the project site. Thus, implementation of a minimum 1,000-foot buffer from a Swainson's hawk nest and consultation with the CDFW on the adequacy of the buffer would ensure impacts are less than significant.

Response to CDFW-5e
The agency recommended mitigation measures for loss of Swainson's hawk foraging habitat of equal to or greater than would be impacted by the proposed project, in perpetuity at a minimum of 1:1. In addition, the CDFW states it must provide written approval of the preserved habitat prior to the start of project activities.

Swainson's hawk foraging habitat is addressed in Master Response 1, which explains why impacts relating to the loss of foraging habitat are less than significant and therefore do not require mitigation under CEQA.

Response to CDFW-6a
The CDFW stated correctly the Draft EIR identified no impacts on tricolored blackbird because there is no suitable nesting habitat on the project site. The CDFW states the project may impact tricolored blackbird within 500 feet of the project site, and if nests are detected and appropriate buffer zones are not established, tricolored blackbird could be disturbed by the project activities resulting in a nest abandonment and loss of egg or reduced health and vigor and loss of young.

The Draft EIR includes MM BIO-4 requiring nesting bird surveys. To clarify the applicability to tricolored blackbirds and in response to CDFW's comment, MM BIO-4 has been revised as follows:

> If construction occurs during the breeding season of migratory and resident birds (February 1 to August 31), a qualified Biologist shall conduct a pre-construction breeding bird survey in areas of suitable habitat within ~~15~~ 7 days prior to the onset of construction activity. ~~Nesting bird surveys shall cover the proposed project footprint and adjacent areas.~~ Surveys shall be conducted within the project footprint and 50 feet from the construction limits for nesting passerines, 250 feet from the construction limits for nesting accipiters, 500 feet for special-status passerine species (e.g., tricolored blackbird), and 1,000 feet from the construction limits for nesting raptors. Where the survey area encroaches onto private property not accessible to the public (e.g., fenced in commercial property, residential backyard, etc.), the qualified Biologist shall either contact the property owner for permission to physically access the property or conduct a visual survey of adjacent areas by scanning with binoculars or a spotting scope. If the survey area is found to be absent of nesting birds, no further mitigation would be required. However, if project activities are delayed by more than 7 days, an additional nesting bird survey shall be performed. If bird nests are found, appropriate buffer zones shall be established around all active nests to protect nesting adults and their young from direct or indirect impacts related to project construction disturbance. Size of buffer zones shall be determined per recommendations of the qualified Biologist based on-site

conditions and species involved. At a minimum a 1,000-foot buffer shall be established for nesting Swainson's hawk and golden eagle; 500-foot buffer for nesting tricolored blackbirds, northern harriers and other non-listed raptors; 250-foot buffer for nesting accipiters; and minimum 50- foot buffers shall be established for nesting passerines and all other non-raptor or passerine nesting birds. If an active nest is located outside of the project site, the buffer shall be extended onto the project site and demarcated where it intersects the project site. Buffer zones shall be maintained until it can be documented that either the nest has failed, or the young have fledged.

Response to CDFW-6b
The CDFW recommended revising MM BIO-4 to include surveys and buffers specific to tricolored blackbird.

CDFW's recommendations have been incorporated into minor revisions to MM BIO-4 to better clarify the mitigation. No changes are proposed or needed to the analysis or impact conclusions. Refer to Response to CDFW-6a.

Response to CDFW-7a
The agency stated a 1,000-foot non-disturbance buffer from an active golden eagle nest identified in MM BIO-1a may not be sufficient to reduce impacts to less than significant, and if appropriate buffer zones are not established around an active golden eagle nest, project impacts to golden eagles would be potentially significant. The agency noted MM BIO-1b also allows modification of the buffer and requested the CDFW be consulted before implementation of a reduced buffer zone to ensure protection of any nesting golden eagles.

MM BIO-1b requires a minimum 1,000-foot non-disturbance buffer from golden eagle nest. The qualified Raptor Biologist can modify (i.e., increase) the size of the buffer to ensure noise or activity from the proposed project would not cause nest disturbance or young or adult bird mortality, but the buffer cannot be reduced below 1,000 feet. MM BIO-1b has been clarified to avoid any ambiguity regarding the manner in which modifications to the default buffer of 1,000 feet could be made:

MM BIO-1b No more than 30 days prior to the first ground disturbance activity, pre-construction golden eagle nesting surveys shall be conducted in the project ~~site~~ vicinity by a qualified Raptor Biologist. The qualified Raptor Biologist shall have at least 2 years of experience surveying for and detecting nesting golden eagles. Pre-construction surveys shall include investigation of all potential nesting trees within a survey area determined by the qualified Raptor Biologist, but no less than a 0.5-mile radius around all project activities. ~~survey area for golden eagle be determined by the qualified Raptor Biologist.~~ If active golden eagle nests are identified within any trees within the survey areas ~~a 0.5-mile radius~~ of the project site, a qualified Raptor Biologist shall establish a protection buffer at a minimum of 1,000 feet that is adequate to ensure noise or activity from the proposed project would not cause nest disturbance or young or adult bird mortality. Buffer zones may vary in size as

> some golden eagles are more acclimated to disturbance than others. Size of buffer zone may be increased ~~modified~~ by the qualified Raptor Biologist considering the type of construction activity that may occur and the behavioral factors and extent that golden eagle may have acclimated to disturbance. No construction or earthmoving activity shall occur within the established buffer zone until it is determined by a qualified Raptor Biologist that the young golden eagles have fledged or that the nesting cycle is complete based on monitoring of the active nest by a qualified Biologist. ~~Surveys shall be conducted by a qualified Raptor Biologist.~~

Response to CDFW-7b
The agency recommended MM BIO-1b be revised to (1) require the survey area for golden eagle be determined by a qualified Raptor Biologist; (2) in consultation with the CDFW; and (3) if any golden eagle nest is identified during pre-construction golden eagle nesting surveys, a biological-based justification for the buffer zone, as determined by the qualified Raptor Biologist, shall be submitted to the CDFW for review, and project activities shall not proceed between March 1 and August 31 unless the CDFW provides written approval of the buffer zone.

Conducting golden eagle surveys does not require obtaining any kind of permit or coordination with the CDFW, and coordination is not warranted to reduce impacts to less than significant. Therefore, requesting written acceptance of the qualified Raptor Biologist conducting the golden eagle survey and providing the survey report to the CDFW for written approval prior to the start of construction is not required under MM BIO-1b.

To address CDFW's comment requiring the survey area for golden eagle be determined by the qualified Raptor Biologist, and to clarify the buffer zone cannot be reduced to less than 1,000 feet, MM BIO-1b shall be revised as shown in CDFW-7a above.

Response to CDFW-8a
The CDFW correctly stated MM BIO-1c requires nesting surveys for northern harrier only within the project site, and the size of the buffer could be modified depending on behavioral factors and acclimation of northern harrier. The CDFW is concerned northern harriers nesting off-site but within 500 feet of the project site may be impacted, and CDFW recommends the CDFW should be consulted before implementing a reduced buffer zone. Additional comments were received suggesting short-eared owl, with habitat requirements and foraging habits similar to northern harrier, should also be included, and the wording of MM BIO 1c has been revised to account for this species as well.

To address CDFW's concern, MM BIO-1c shall be revised as follows:

> Prior to ground disturbance, a pre-construction nesting survey shall be conducted for northern harrier and short-eared owl by a qualified Raptor Biologist if construction is scheduled during the nesting season (February 1 through September 1). The qualified Raptor Biologist shall have at least 2 years of experience surveying for and detecting nesting northern harrier and short-eared owl. To determine whether northern harrier or short-eared owl is nesting on-site, a qualified Raptor

Biologist(s) shall conduct walking transects through the project site grassland habitat searching for nests and within a minimum 500-foot radius from the project site. Where the survey area encroaches onto private property not accessible to the public (e.g., fenced in commercial property, residential backyard, etc.), the qualified Biologist shall either contact the property owner for permission to physically access the property or conduct a visual survey of adjacent areas by scanning with binoculars or a spotting scope. An active northern harrier or short-eared owl nest must be protected by implementing a minimum 500-foot radius buffer zone around the nest marked with orange construction fencing. If an active nest is located outside of the project site, the buffer shall be extended onto the project site and demarcated where it intersects the project site. Size of buffer zone could be ~~modified~~ increased considering the type of construction activity that may occur, physical barriers between the construction site and active nest, and the behavioral factors and extent that northern harrier or short-eared owl may have acclimated to disturbance. No construction or earthmoving activity shall occur within the established buffer zone until it is determined by a qualified Raptor Biologist that the young have fledged or that the nesting cycle is otherwise determined to be complete based on monitoring of the active nest by a qualified Raptor Biologist.

Response to CDFW-8b

The CDFW provided recommendations to reduce impacts to northern harrier to less than significant. Recommendations included revisions to MM BIO-1c to require submission of biological-based justification for reducing the buffer zone, as determined by the qualified Raptor Biologist, to the CDFW for review. The CDFW also stated work activities could not commence until the CDFW provides written approval for the reduction of the non-disturbance buffer zone. Additionally, the CDFW recommended revising MM BIO-1c to state surveys shall be conducted within a minimum 500-foot radius of the project site.

As indicated in Response to CDFW-8a, MM BIO-1c has been revised to clarify the "minimum" buffer requirement and ensure surveys are conducted a minimum 500-foot radius from the construction limits project.

Response to CDFW-9a

The CDFW states MM BIO-1d requirements to conduct burrowing owl surveys 2 weeks prior to project construction and a 100-foot non-disturbance buffer may not be adequate to detect burrowing owls and avoid project impacts to burrowing owls, including permanent reduction of burrowing owl habitat in Napa County.

MM BIO-1d requires a minimum 100-foot buffer zone, which means the qualified Raptor Biologist could require a larger buffer if it is determined, by the Raptor Biologist, that a larger buffer is warranted to avoid project impacts that could result in nest abandonment, loss of young, and/or injury or mortality of burrowing owls.

As discussed in Draft EIR Section 3.3, Biological Resources, page 3.3-17, pre-construction surveys, referred to as "take avoidance surveys" in the CDFW 2012 Staff Report on Burrowing Owl Mitigation

(2012 Staff Report), are intended to detect presence of burrowing owl on a project site at a fixed period in time and inform necessary take avoidance actions. Take avoidance surveys may detect changes in owl presence such as colonizing burrowing owl that have recently moved onto the site, migrating owl, resident burrowing owl changing burrow use, or young of the year that are still present and have not dispersed. In summary, survey methodology for pre-construction surveys should be conducted no less than 14 days prior to initiating ground disturbance activities according to the CDFW Staff Report. Consistent with the 2012 Staff Report, MM BIO-1d requires that pre-construction surveys shall be conducted within 2 weeks prior to onset of any ground-disturbing activities. Implementation of pre-construction surveys conducted within 2 weeks prior to onset of any ground-disturbing activities would detect whether burrowing owls were present on-site, allowing avoidance measures, such as a minimum 100-foot buffer, to be implemented thus ensuring no burrowing owl would be impacted by construction activities.

Response to CDFW-9b
The CDFW recommends MM BIO-1d be revised to require a habitat assessment be conducted within 500 meters of the project site, and if warranted based on the habitat assessment breeding and nonbreeding surveys be conducted within 500 meters of the project site in conformance with the 2012 Staff Report.

The biological resource report referenced in the Draft EIR made an assessment that the project site did not support suitable habitat for burrowing owl. This assessment demonstrated that, based on the absence of suitable habitat on the project site due to general lack of California ground squirrel and ground squirrel colonies, and the fact no burrowing owl were observed during several biological field surveys conducted by Huffman-Broadway Group (HBG) Biologists between December 2020 and April 2021, Helm Biological Consulting in December 2020 and April and May 2021, or during previous biological studies conducted by Monk & Associates, LSA Associates, or Rana Resources, and that the nearest burrowing owl recorded in the California Natural Diversity Database (CNDDB) is 1.7 miles from the project site, breeding and nonbreeding surveys are not warranted.

It should be noted the 2012 Staff Report recommends conducting surveys and habitat assessments within 150 meters of the project site, not 500 meters as referenced by the CDFW. To address CDFW's concern, and ensure any burrowing owl that may be within the project site or adjacent to the project site are not impacted by project activities, the first paragraph of MM BIO-1d shall be revised as follows:

> Prior to any ground disturbance, pre-construction surveys for burrowing owl shall be conducted <u>within a minimum of 150 meters of the project site. Where the survey area encroaches onto private property not accessible to the public (e.g., fenced in commercial property, residential backyard, etc.), the qualified Biologist shall either contact the property owner for permission to physically access the property or conduct a visual survey of adjacent areas by scanning with binoculars or a spotting scope.</u> The pre-construction surveys shall be conducted within 2 weeks prior to the onset of any ground-disturbing activities. Surveys shall be conducted by a qualified Biologist following California Department of Fish and Wildlife (CDFW) 2012 Staff

Report survey methods and Biologist qualifications to establish the status of burrowing owl on the project site.

- If burrowing owl are found to occupy the project site during the nonbreeding season (September 1 to January 31), occupied burrows shall be avoided by establishing a no-disturbance buffer zone a minimum of 100 feet around the burrow. Buffers may be adjusted to address site-specific conditions using the impact assessment approach described in the CDFW 2012 staff report. If a qualified Raptor Biologist determines the location of an occupied burrow/s may be impacted even with a 100-foot buffer, or the burrow(s) are in a location(s) on the project site where a buffer cannot be established without preventing the proposed project from moving forward, then a passive relocation effort may be instituted to relocate the individual(s) out of harm's way pursuant to a Burrowing Owl Exclusion Plan prepared in accordance with the CDFW 2012 staff report.
- If burrowing owl are found to be present during the breeding season (February 1 to August 31), the proposed project ground-disturbing activities shall follow the CDFW 2012 staff report recommended avoidance protocol whereby occupied burrows shall be avoided with a no-disturbance buffer.
- If burrowing owls are ultimately found on the site and burrow eviction/ relocation of burrowing owls during the non-nesting season is a selected strategy to move forward with the project without direct impacts to burrowing owl individuals, the applicant shall coordinate this effort with CDFW and provide habitat mitigation consistent with the 2012 CDFW Staff Report on burrowing owl.

The CDFW indicates that habitat compensation mitigation would be required for evictions of a burrowing owl from its shelter, impacting an unoccupied nesting burrowing owl burrow or burrow surrogate or an occupied burrow, and that habitat mitigation shall be approved by CDFW prior to the start of construction. The CDFW provides mitigation ratios for impacts to each nest site and burrowing owl foraging habitat.

The Draft EIR acknowledged the proposed project would preserve in perpetuity, using a deed restriction or conservation easement, approximately 45 acres of open space abutting the project site. This 45-acre open space area would provide similar habitat as the project site for burrowing owl. In addition the Draft EIR acknowledges the Napa Logistics Park Project has preserved 37 acres of grassland and wetlands in perpetuity that provides similar habitat as what is found on the project site, and there are several large open space preserves including the 620-acre Newell Open Space less than 2 miles from the project site, the 1,039-acre Lynch Canyon Open Space Park, and the 308-acre American Canyon red-legged frog preserve, all within 2-5 miles of the project site. A small number of burrowing owl have been recorded in the CNDDB within the general project vicinity, with the nearest reports from as close as about 1.7 miles north of the project site and about 2.5 miles to the south. This demonstrates that, based upon the limited number of known burrowing owls to occur within a 2.5-mile radius of the project site and the acreage of existing foraging habitat currently protected, there is more than sufficient foraging and nesting habitat near the project site. Accordingly, the proposed project would not result in significant impacts to foraging or nesting habitat nor affect the nesting populations of burrowing owl near the project site either directly, indirectly, or cumulatively,

nor require habitat compensation for evictions of a burrowing owl from its shelter, impacting an unoccupied nesting burrowing owl burrow or burrow surrogate or an occupied burrow, or foraging habitat should a burrowing owl be located on or adjacent to the project site.

It should be noted that, if burrowing owls are ultimately found on the site and burrow eviction/ relocation of burrowing owls during the non-nesting season is a selected strategy to move forward with the project without direct impacts to burrowing owl individuals, the applicant will coordinate this effort with CDFW and provide habitat mitigation consistent with the 2012 CDFW Staff Report on burrowing owl, as indicated by the third bullet in the modified MM BIO-1d shown above.

The operative significance threshold for impacts to burrowing owls, an unlisted species, is whether the proposed project would have a substantial adverse effect on the species, either directly or through habitat modifications. Although the proposed project would result in a net loss of potential burrowing owl foraging habitat, such a net loss occurring in the particular area in which the project site is located will not cause a substantial adverse effect on the species. There is no need to "net out the impact of a proposed project" for that impact to be less than significant. (See, *Save Panoche Valley v. San Benito County* (2013) 217 Cal.App.4th 503, 529.)

Response to CDFW-10
The agency requested clarification about the development footprint for the project-level component and the program-level component.

Phase 1, the project-level component, totals 94.7 acres. The applicant proposes to develop 1,097,488 square feet of high-cube warehouse on 70.2 acres and preserve the remaining 24.5 acres as open space.

Phase 2, the program-level component, totals 113.1 acres. The applicant proposes to develop up to 1.3 million square feet of high-cube warehouse on this site on approximately 92 acres and preserve the remaining approximately 21 acres. Because wetlands are located throughout Phase 2, the layout will be dependent on the outcome of the permitting process with the resource agencies. Hence, those acreage values are subject to change.

Response to CDFW-11
The agency requested clarification about how much of the project site would be developed.

As indicated in Response to CDFW-10, 70.2 acres would be developed in Phase 1 and approximately 92 acres would be developed in Phase 2, for a combined total of approximately 163 acres.

Response to CDFW-12
The agency requested that a site plan be provided.

The site plan is provided in Draft EIR Chapter 2, Project Description, Exhibit 2-4. As shown in the exhibit, the layout for Phase 1 is shown but no layout is shown for Phase 2 because it will depend on the aforementioned permitting process.

Response to CDFW-13
The agency provided standard language about environmental data. No response is necessary.

Response to CDFW-14
The agency provided standard language about Notice of Determination filing fees. No response is necessary.

Response to CDFW-15
The agency provided closing remarks. No response is necessary.

Subject: **Draft Environmental Impact Report (DEIR) (SCH # 2021010104)**
Giovannoni Logistics Center Project Fiscal Impact Analysis

Dear Mr. Cooper,

The American Canyon Fire Protection District appreciates the opportunity to provide comment on the fiscal impacts of the proposed 2.4 million square foot Giovannoni Logistics Center Project on District operations and capital facility needs. The project calls for a high cube warehouse on a 208-acre site.

Based upon a fiscal analysis prepared by the developer's consultant, and reviewed by the District, the annual cost of providing fire suppression and EMS services to the Project is expected to exceed the property tax and fire service fee revenue generated from the Project by approximately $158,000; and this annual operating deficit will continue to increase over time as the growth in the cost of providing fire and EMS services is projected to outpace the growth in revenue due to the 2% cap on property tax increases imposed by Proposition 13.

1

A potential mitigation measure discussed with the developer to address the annual operating deficit involved the formation of a benefit assessment district that would provide the District with a source of additional, ongoing revenue. The developer suggested that the funds from this benefit assessment district could be used to negotiate down a portion of the fire mitigation fees and other related development fees that would be payable to the Fire District prior to construction of this project. The operational impacts of a project of this magnitude will be significant to the Fire District. It is imperative that the gap between the annual cost of providing fire and ems services to this proposed project and the estimated property tax it is expected to generate be bridged as a condition of approval prior to construction.

This Project, along with other current and planned development within the District's service area will trigger the need for a new "north" fire station and related apparatus. The District has adopted fire mitigation fees to address the cumulative impact of new development on need for new and expanded capital facilities. Based on the Fiscal Year 2021-22 per square foot mitigation

DocuSign Envelope ID: 529D8DF3-2BE8-469E-9B6E-866536137A1D

fee, the Project would contribute a "fair share" amount of $2.5 million in revenue toward the cost of new facilities.

The Fire District looks forward to working both with the developer and the City as this project progresses through the current development approval process.

Fire Chief

Local Government

American Canyon Fire Protection District–ACFPD

Response to ACFPD-1

ACFPD provided introductory remarks and indicated that the proposed project's revenues would not be enough to offset its demand, which would result in an annual operating deficit. ACFPD identified the establishment of benefit assessment district as a potential solution for this issue. In addition, the Fire Protection District indicated that the proposed project, along with other planned development, would trigger the need for a "North" fire station and related apparatus. The ACFPD noted that the proposed project would contribute $2.5 million in one-time fees toward the cost of new facilities.

Fiscal impacts are outside the scope of the Draft EIR as they do not have physical impacts on the environment.

The new "North" fire station is addressed in Master Response 2.

RE: Giovannoni Logistics Center Project YD-02052021-03

Dear Mr. Cooper:

Thank you for your project notification letter dated, May 20, 2022, regarding cultural information on or near the proposed Giovannoni Logistics Center Project. We appreciate your effort to contact us and wish to respond.

The Cultural Resources Department has reviewed the project and concluded that it is within the aboriginal territories of the Yocha Dehe Wintun Nation. Therefore, we have a cultural interest and authority in the proposed project area and would like to continue to receive updates on the project. In addition, please see the attached document with our suggested edits to the Draft EIR.

Should you have any questions, please contact:

CRD Administrative Staff
Yocha Dehe Wintun Nation
Office: (530) 796-3400
Email: THPO@yochadehe-nsn.gov

1

Please refer to identification number YD – 02052021-03 in any correspondence concerning this project.

Thank you for providing us the opportunity to comment.

Sincerely,

Impacts	Mitigation Measures	Level of Significance After Mitigation
Impact CUL-2: The proposed project could cause a substantial adverse change in the significance of an archaeological resource pursuant to Section 15064.5.	**MM CUL-2a:** No ground disturbance shall take place within 100 feet of informal archaeological resource 483A-001. The resource shall be preserved in place. **MM CUL-2b:** An Archaeologist who meets the Secretary of the Interior's Professional Qualification Standards for archaeology shall be present on-site during all earth disturbing activities. If prehistoric or historic-period archaeological resources are encountered, all construction activities within 100 feet of the find shall halt and the City of American Canyon shall be notified. Prehistoric archaeological materials may include obsidian and chert flaked stone tools (e.g., projectile points, knives, scrapers) or toolmaking debris; culturally darkened soil ("midden") containing heat-affected rocks, artifacts, or shellfish remains; and stone milling equipment (e.g., mortars, pestles, hand stones, or milling slabs); and battered stone tools, such as hammerstones and pitted stones. Historic-period materials might include stone, concrete, or adobe footings and walls; filled wells or privies; and deposits of metal, glass, and/or ceramic refuse. The Archaeologist shall inspect the findings within 24 hours of discovery. If it is determined the project could damage a historical resource or a unique archaeological resource (as defined pursuant to the CEQA Guidelines), mitigation shall be implemented in accordance with Public Resources Code Section 21083.2 and Section 15126.4 of the CEQA Guidelines, with a preference for preservation in place. Consistent with Section 15126.4(b)(3), this may be accomplished through planning construction to avoid the resource; incorporating the resource within open space; capping and covering the resource; or deeding the site into a permanent conservation easement. If avoidance is not feasible, a qualified Archaeologist shall prepare and implement a detailed treatment plan in consultation with the City of American Canyon. Treatment of unique archaeological resources shall follow the applicable requirements of Public Resources Code Section 21083.2. Treatment for most resources would consist of (but would not be limited to) sample excavation, artifact collection, site documentation, ~~and historical research~~, with the aim to target the recovery of important scientific data contained in the portion(s) of the significant resource to be impacted by the proposed project. The treatment plan shall include provisions for analysis of data in a regional context, reporting of results	Less than significant impact.

Subject: Comments on Giovannoni Logistics Center EIR (SCH No. 2021010104)

Dear Ms. Jones,

Thank you for the opportunity to comment on the Environmental Impact Report (EIR) for the proposed Giovannoni Logistics Center Project. Please accept and consider these comments on behalf of Golden State Environmental Justice Alliance (GSEJA). Also, GSEJA formally requests to be added to the public interest list regarding any subsequent environmental documents, public notices, public hearings, and notices of determination for this project. Send all communications to Golden State Environmental Justice Alliance P.O. Box 79222 Corona, CA 92877.

1.0 Summary

1

The project proposes the construction and operation of a 2.4 million square foot logistics center on approximately 163 acres of the approximately 208-acre project site. The remaining 44.8 acres would be preserved as open space/wetland preserve. Phase 1 consists of approximately 1.1 million square feet on the eastern portion of the project site. This area will support two high-cube warehouse buildings totaling 1,069,904 square feet. One of the buildings would be rail-served by the adjacent Napa Branch Line.
Phase 2 consists of approximately 1.3 million square feet industrial uses on the western portion of the project. Approximately 45 acres of the project site would be preserved as wetlands. The project would extend the Napa Valley Vine Trail along the project frontage with Devlin Road and Green Island Road.

3.2 Air Quality and 3.6 Greenhouse Gas Emissions and Energy

Please refer to attachments from SWAPE for a complete technical commentary and analysis.

The EIR does not include for analysis relevant environmental justice issues in reviewing potential impacts, including cumulative impacts from the proposed project. This is especially significant as the surrounding community is highly burdened by pollution. According to CalEnviroScreen 4.0[1], CalEPA's screening tool that ranks each census tract in the state for pollution and socioeconomic vulnerability. The proposed project's census tract (6055201005) and surrounding community, including residences to the east and south, bears the impact of multiple sources of pollution and is more polluted than average on several pollution indicators measured by CalEnviroScreen. For example, the project census tract ranks in the 83rd percentile for traffic impacts, which are typically attributed to heavy truck activity in the area. 2a

The census tract also ranks in the 84th percentile for solid waste facility impacts, which can expose people to hazardous chemicals, release toxic gases into the air (even after these facilites are closed), and chemicals can leach into soil around the facility and pose a health risk to nearby populations[2]. The census tract also ranks in the 61st percentile for toxic releases and 83rd percentile for hazardous waste impacts. People living near facilities that emit toxic releases may breathe contaminated air regularly or if contaminants are released during an accident[3]. Hazardous waste generators and facilities contribute to the contamination of air, water and soil near waste generators and facilities can harm the environment as well as people[4]. 2b

Further, the census tract is a diverse community including 31% Asian-American, 30% Hispanic, and 3% African-American residents, which are especially vulnerable to the impacts of pollution. The community is also economically disadvantaged. The community has a high rate of low educational attainment, meaning 62% of the census tract over age 25 has not attained a high school diploma, which is an indication that they may lack health insurance or access to medical care. Medical care is vital for this census tract as it ranks in the 72nd percentile for incidence of asthma and 67th percentile for incidence of cardiovascular disease. 2c

[1] CalEnviroScreen 4.0 https://oehha.ca.gov/calenviroscreen/report/calenviroscreen-40
[2] OEHHA Solid Waste Facilities https://oehha.ca.gov/calenviroscreen/indicator/solid-waste-sites-and-facilities
[3] OEHHA Toxic Releases https://oehha.ca.gov/calenviroscreen/indicator/toxic-releases-facilities
[4] OEHHA Hazardous Waste Generators and Facilities https://oehha.ca.gov/calenviroscreen/indicator/hazardous-waste-generators-and-facilities

The State of California lists three approved energy compliance modeling softwares[5] for non-residential buildings: CBECC-Com, EnergyPro, and IES VE. CalEEMod is not listed as an approved software. The spreadsheet-based modeling energy calculations in Appendix B do not comply with the 2019 Building Energy Efficiency Standards and under reports the project's potentially significant GHG and Energy impacts to the public and decision makers. Since the EIR did not accurately or adequately model the energy impacts in compliance with Title 24, a finding of significance must be made. A revised EIR with modeling in one of the approved software types must be circulated for public review in order to adequately analyze the project's potentially significant environmental impacts. This is vital as the EIR utilizes CalEEMod as a source in its methodology and analysis, which is clearly not one of the approved softwares. 2d

The EIR concludes that the project will not result in significant GHG impacts because it incorporates design and operational features listed within the BAAQMD's 2022 GHG significance thresholds[6][7]. To achieve less-than-significant status with BAAQMD's threshold, the EIR states that the project complies with the requirement to "Achieve a reduction in project-generated vehicle miles traveled (VMT) below the regional average." However, the Transportation analysis has not analyzed all project-generated VMT. The VMT analysis excludes medium and heavy duty trucks. As stated below in the Transportation discussion, the VMT analysis must be revised to include medium and heavy duty trucks in order to adequately and accurately analyze all project-generated VMT. The operational nature of industrial/warehouse uses involves high rates of medium and heavy duty truck/trailer/freight VMT due to traveling from large regional distribution centers to smaller industrial parks and then to their final delivery destinations. The project's medium and heavy duty truck/trailer/freight activity is unable to utilize public transit or active transportation 2e

[6] Bay Area Air Quality Management District Proposed CEQA Thresholds for Evaluating the Significance of Climate Impacts from Land Use Projects and Plans https://civicclerk.blob.core.windows.net/stream/BAAQMDCA/1af1b756-8b30-4ae3-944c-1e6b0e8aff57.pdf?sv=2015-12-11&sr=b&sig=YmFQ4LihGdULeofmf1l0zKrDbLtORYvh4uBi5crXdhQ%3D&st=2022-06-07T19%3A45%3A42Z&se=2023-06-07T19%3A50%3A42Z&sp=r&rscc=no-cache&rsct=application%2Fpdf

[7] Bay Area Air Quality Management District Justification Report: CEQA Thresholds for Evaluating the Significance of Climate Impacts from Land Use Projects and Plans https://civicclerk.blob.core.windows.net/stream/BAAQMDCA/d1ba3e75-3e5f-428b-8f16-f5d5a84d651c.pdf?sv=2015-12-11&sr=b&sig=d%2FWhTNJXu9oSDOoyP8Jgml%2FwPOzGx4iZ%2FRq9BOqJNy0%3D&st=2022-06-07T19%3A36%3A50Z&se=2023-06-07T19%3A41%3A50Z&sp=r&rscc=no-cache&rsct=application%2Fpdf

and it is misleading to the public and decision makers to exclude this activity from VMT analysis. A revised EIR must be prepared to reflect a quantified VMT analysis that includes all medium and heavy duty truck/trailer/freight activity to adequately and accurately analyze the potentially significant project transportation impacts. The revised VMT analysis must be utilized to revise the GHG analysis to determine if the project-generated VMT is 15% below the prescribed threshold. 2e

Additionally, as discussed throughout this comment letter, the EIR relies upon the combined workforce of Napa and Solano Counties to fill the project's operational jobs. Relying upon the entire labor force of Napa and Solano Counties greatly exceeds the 16.24 miles of VMT per employee utilized by the Transportation analysis to determine the project will not have a significant impact on VMT. Napa County is 789 square miles in area and Solano County is 906 square miles in area. Relying on the entire labor force of Napa and Solano Counties to fill the project's construction and operational jobs will increase VMT and GHG emissions during all phases of construction and operations and the GHG analysis must be revised to account for longer worker trip distances. 2f

3.9 Land Use

Table 3.9-2: General Plan Consistency Analysis provides misleading consistency analysis with General Plan goals, policies and objectives adopted with the purpose of avoiding or mitigating an environmental effect, including the following:

Objective 1.2 Promote a rate of growth that is consistent with the ability of the City to provide adequate infrastructure and services and does not adversely impact the distinctive character and quality of life in American Canyon. 3a

EIR Analysis
Consistent: The proposed project would develop 2.4 million square feet of new industrial uses on a site designated for such use located within the American Canyon city limits. The project site is located within the Green Island Business Park and is surrounded by urban uses and infrastructure on three sides. Thus, the proposed project would occur in an area where adequate infrastructure and services exist such that it would not exceed the City's ability to serve it.

Comments: See discussion below regarding Land Use Element Page 1-12: Development Capacity Table.

Objective 3.4 Increase the number of firms within the industries now represented in the City and capture new, clean, nonpolluting industries that are stable and compatible with City needs in terms of traffic, air quality, and employment. 3b

EIR Analysis
Consistent: The proposed project would develop 2.4 million square feet of high-cube warehouse on an approximately 208-acre site in the Green Island Business Park. These types of uses currently exist within the Airport Industrial Area. Additionally, the proposed project is estimated to create 3,643 new jobs. The proposed project would implement traffic improvements to mitigate for impacts on traffic operations.

3b

Comments: The EIR concludes the project will result in significant and unavoidable cumulatively considerable impacts to Air Quality. The EIR must be revised to include this fact for consistency analysis and including a finding of significance due to inconsistency with this objective.

Circulation Element Policy 1.11 Reduce Vehicle Miles Traveled. Through layout of land uses, improved alternate modes, and provision of more direct routes, strive to reduce the total vehicle miles traveled by City residents.

EIR Analysis
Consistent: The project site is located within the Napa County Airport Industrial Area, which has convenient access to SR-12 and SR-29. The development of the proposed project's 2.4 million square feet of high-cube warehouse is within the North Bay Region and would contribute to reducing trip length by locating these facilities closer to customers within this region. Finally, the development of up to 3,643 new jobs in a housing-rich part of the Bay Area region would allow employees to work closer to where they live, thereby reducing vehicle miles traveled.

Comments: As stated below in the Transportation analysis, the VMT analysis does not analyze all project-generated VMT. The VMT must be revised to include medium and heavy duty trucks in order to adequately and accurately analyze <u>all project-generated</u> VMT. The operational nature of industrial/warehouse uses involves high rates of medium and heavy duty truck/trailer/freight VMT due to traveling from large regional distribution centers to smaller industrial parks and then to their final delivery destinations. The project's medium and heavy duty truck/trailer/freight activity is unable to utilize public transit or active transportation and it is misleading to the public and decision makers to exclude this activity from VMT analysis. A revised EIR must be prepared to reflect a quantified VMT analysis that includes all medium and heavy duty truck/trailer/freight activity to adequately and accurately analyze the potentially significant project transportation impacts. The revised VMT analysis must be utilized to revise the GHG analysis to determine if the project-generated VMT is 15% below the prescribed threshold.

3c

Additionally, the EIR excludes analysis of the following General Plan goals, policies and objectives adopted with the purpose of avoiding or mitigating an environmental effect, including the following:

3d

Land Use Policy 1.3.4 Limit the total additional new development that can be accommodated in the City and its Urban Limit Line to the following provided that the highway improvements stipulated by the Circulation Element are implemented.

Land Use Element Page 1-12: Development Capacity Table

3d

Industrial Development

City: 1,560,195 square feet

City Urban Limit Line: 4,218,305 square feet

Total: 5,778,500 square feet

Land Use Goal 1T Establish a City Urban Limit Line for the City of American Canyon which describes its future geographic boundary until January 1, 2030.

3e

Land Use Policy 1.22.9 Control, through the permit process, the development of industrial uses that use, store, produce, or transport hazardous materials in threshold planning quantities, generate unacceptable levels of noise or air emissions, or result in other impacts that adversely impact American Canyon.

3f

Economic Development Objective 3.2 Promote growth that generates net positive fiscal impacts to the City to ensure that municipal services keep up with growing demand.

3g

Economic Development Policy 3.2.1 Evaluate the need for, and implement as necessary, a fiscal impact analysis as part of the Project Development Review process for certain types of projects. The purpose is to provide input into assessment of Citywide impact of development activities and to determine what costs to the City, if any, may be subject to mitigation.

3h

Due to the project's proposal to construct 2.4 million square feet of industrial warehousing that results in significant and unavoidable Air Quality impacts (including inconsistency with the Bay Area AQMD Air Quality Plan), and errors in modeling and modeling without supporting evidence, as noted throughout this comment letter and attachments, the proposed project is directly inconsistent with the goals, policies and objectives listed above adopted with the purpose of avoiding or mitigating an environmental effect. The EIR must be revised to include a consistency analysis with all General Plan goals, policies and objectives in order to provide an adequate and accurate environmental analysis.

3i

Particularly of note is the General Plan Land Use Element Page 1-12: Development Capacity Table. According to Figure 3: Planning Area of the General Plan Introduction Section, the project site is located in the City Urban Limit area. The project proposes 2.4 million square feet of industrial development, which is approximately 56% of the industrial development capacity in the

3j

City Urban Limit area and approximately 41.5% of all industrial development capacity in both the City Limit and City Urban Limit area. The EIR does not provide a list of cumulative industrial projects approved since the 1994 approval of the General Plan within the City Limits and City Urban Limit areas. The General Plan industrial development capacity is not discussed or presented for analysis in the EIR and must be included as part of a revised and recirculated EIR for public review. A finding of significance must be made if it is determined that the proposed project exceeds the General Plan development capacity for industrial uses. 3j

3.12 Transportation

Appendix H: Transportation sources the Governor's Office of Planning and Research (OPR) 2018 CEQA Guidelines Update and Technical Advisory as contributing to the methodology for VMT analysis. The VMT analysis does not state if medium and heavy duty truck/trailer trips were included for analysis. The EIR does not provide a statutory source of exemption for medium/heavy trucks. The EIR sources the OPR's 2018 Technical Advisory[8] which states that "here, the term "automobile" refers to on-road passenger vehicles, specifically cars and light trucks." However, the purpose of the OPR Technical Advisory document is purely advisory, stating in its introduction:

"The purpose of this document is to provide advice and recommendations, which agencies and other entities may use at their discretion. This document does not alter lead agency discretion in preparing environmental documents subject to CEQA. This document should not be construed as legal advice." 4

The OPR document is not a legal interpretation, court decision, or amendment to the CEQA statute that clarifies the definition of automobile. The term "automobile" is not defined in the CEQA statute and application of the OPR interpretation is speculative and does not provide an analysis of the "worst-case scenario" for environmental impacts. Widespread public understanding and perception indicates that trucks, including medium/heavy-duty truck/trailer trips associated with the industrial nature of warehouse operations, are automobiles. The EIR must be revised to include all truck/trailer activity for quantified VMT analysis. The operational nature of industrial/warehouse uses involves high rates of truck/trailer VMT due to traveling from large regional distribution centers to smaller industrial parks and then to their final delivery destinations. The project's truck/trailer activity is unable to utilize public transit or active transportation and it

[8] Governor's Office of Planning and Research Technical Advisory on Evaluating Transportation Impacts in CEQA https://opr.ca.gov/ceqa/docs/20190122-743_Technical_Advisory.pdf

is misleading to the public and decision makers to exclude this activity from VMT analysis. A revised EIR must be prepared to reflect a quantified VMT analysis that includes all truck/trailer activity to adequately and accurately analyze the potentially significant project transportation impacts. 4a

Further, the EIR states that "According to Statewide Travel Demand Model estimates, this project is located within a Traffic Analysis Zone (TAZ) with a projected VMT per employee of 16.24 miles." However, the Statewide TDM software utilized is not included as a reference. The EIR must be revised to state the name of the Statewide TDM utilized and also provide a weblink to the software in order to comply with CEQA's requirements for meaningful disclosure and incorporation by reference because the Statewide TDM contributes directly to analysis of the problem at hand (CEQA § 15150 (f)). 4b

Notably, the EIR concludes that the project will not have significant VMT impacts because the project is located within a TAZ with a projected VMT per employee of 16.24 miles. However, Section 6.2: Growth Inducing Impacts relies upon the combined Napa County and Solano County labor force of 273,500 people to conclude that "unplanned growth would not occur." Relying upon the entire labor force of Napa and Solano Counties greatly exceeds the 16.24 miles of VMT per employee utilized by the Transportation analysis to determine the project will not have a significant impact on VMT. Napa County is 789 square miles in area and Solano County is 906 square miles in area. Relying on the entire labor force of Napa and Solano Counties to fill the project's construction and operational jobs will increase VMT and emissions during all phases of construction and operations and the EIR must be revised to account for longer worker trip distances. 4c

Further, because the "City of American Canyon has not yet established thresholds of significance related to VMT," the EIR utilizes "established policies currently used by OPR, Sacramento County and the City of San Jose" in order to invent the threshold that "a VMT impact would be identified at an industrial project if the project VMT per employee is higher than the regional average VMT per employee." However, the specific policies and associated documents from OPR, Sacramento County and the City of San Jose are not included in the EIR. This does not comply with CEQA's requirements for meaningful disclosure and incorporation by reference. The EIR must be revised to attach the specific policies and associated documents from OPR, Sacramento County and the City of San Jose in order to comply with CEQA's requirements for meaningful disclosure and incorporation by reference because the policies and documents contribute directly to analysis of 4d

the problem at hand (CEQA § 15150 (f)). Without these items, the public is unable to verify the accuracy of the VMT analysis and the EIR cannot conclude the VMT impacts are not significant. 4d

4.0 Cumulative Effects

4.2 Cumulative Impact Analysis

The EIR has not adequately or accurately provided a cumulative impact analysis. For example, the EIR has not analyzed the project in accordance with General Plan Land Use Element Page 1-12: Development Capacity Table. According to Figure 3: Planning Area of the General Plan Introduction Section, the project site is located in the City Urban Limit area. The project proposes 2.4 million square feet of industrial development, which is approximately 56% of the industrial development capacity in the City Urban Limit area and approximately 41.5% of all industrial development capacity in both the City Limit and City Urban Limit area. The EIR does not provide a list of cumulative industrial projects approved since the 1994 approval of the General Plan within the City Limits and City Urban Limit areas. The General Plan industrial development capacity is not discussed or presented for analysis in the EIR and must be included as part of a revised and recirculated EIR for public review. A finding of significance must be made if it is determined that the proposed project exceeds the General Plan development capacity for industrial uses. 5a

Additionally, the EIR does not discuss the cumulative growth impacts of the proposed project on the Bay Area. The Association of Bay Area Governments (ABAG) Plan Bay Area 2050's Growth Pattern[9] notes that the South Napa County area (Napa City and American Canyon City combined) will add 19,000 jobs between 2015 - 2050. Utilizing the EIR's calculation of 3,643 employees, the project represents 19% of South Napa County's employment growth from 2015 - 2050. Plan Bay Area 2050's Growth Pattern notes that the South Napa County's population will increase by 5,000 residents between 2015 - 2050. Utilizing the EIR's calculation of 3,643 employees, the project represents 72% of South Napa County's population growth from 2015 - 2050. A single project accounting for this amount of the projected employment and/or population over 35 years represents a significant amount of growth. The EIR must be revised to include this analysis, and also provide a cumulative analysis discussion of projects approved since 2015 and projects "in the pipeline" in American Canyon and City of Napa to determine if the project will exceed Plan Bay Area 2050's employment and/or population growth forecast for South Napa County. 5b

5.0 Alternatives

[9] Plan Bay Area 2050 Growth Pattern
https://www.planbayarea.org/sites/default/files/FinalBlueprintRelease_December2020_GrowthPattern_Jan2021Update.pdf 6

The EIR is required to evaluate a reasonable range of alternatives to the proposed project which will avoid or substantially lessen any of the significant effects of the project (CEQA § 15126.6.)

The EIR does not evaluate a reasonable range of alternatives as it does not include an alternative that meets the project objectives and also eliminates all of the project's significant and unavoidable impacts. The EIR must be revised to include analysis of a reasonable range of alternatives and 6

foster informed decision making (CEQA § 15126.6). This must include alternatives such as development of the site with a project that reduces all of the proposed project's significant and unavoidable impacts to less than significant levels.

6.0 Other CEQA Considerations

6.2 Growth Inducing Impacts

The EIR does not discuss General Plan Land Use Element Page 1-12: Development Capacity Table. According to Figure 3: Planning Area of the General Plan Introduction Section, the project site is located in the City Urban Limit area. The project proposes 2.4 million square feet of industrial development, which is approximately 56% of the industrial development capacity in the City Urban Limit area and approximately 41.5% of all industrial development capacity in both the City Limit and City Urban Limit area. The EIR does not provide a list of cumulative industrial projects approved since the 1994 approval of the General Plan within the City Limits and City Urban Limit areas. The General Plan industrial development capacity is not discussed or presented for analysis in the EIR and must be included as part of a revised and recirculated EIR for public review. A finding of significance must be made if it is determined that the proposed project exceeds the General Plan development capacity for industrial uses. 7a

Additionally, the EIR does not discuss the cumulative growth impacts of the proposed project on the Bay Area. The Association of Bay Area Governments (ABAG) Plan Bay Area 2050's Growth Pattern[10] notes that the South Napa County area (Napa City and American Canyon City combined) will add 19,000 jobs between 2015 - 2050. Utilizing the EIR's calculation of 3,643 employees, the project represents 19% of South Napa County's employment growth from 2015 - 2050. Plan Bay Area 2050's Growth Pattern notes that the South Napa County's population will increase by 5,000 residents between 2015 - 2050. Utilizing the EIR's calculation of 3,643 employees, the 7b

[10] Plan Bay Area 2050 Growth Pattern
https://www.planbayarea.org/sites/default/files/FinalBlueprintRelease_December2020_GrowthPattern_Jan2021Update.pdf

project represents 72% of South Napa County's population growth from 2015 - 2050. A single project accounting for this amount of the projected employment and/or population over 35 years represents a significant amount of growth. The EIR must be revised to include this analysis, and also provide a cumulative analysis discussion of projects approved since 2015 and projects "in the pipeline" in American Canyon and City of Napa to determine if the project will exceed Plan Bay Area 2050's employment and/or population growth forecast for South Napa County. 7b

The EIR relies upon the notion that project's buildings "*likely* be built incrementally over a period of years and, thus, jobs would be added in blocks as the project builds out. As such, there would not be an "overnight" influx of new employment opportunities." However, utilizing an incremental construction schedule is not internally consistent with the EIR's other areas of analysis. For example, the Air Quality analysis models a construction schedule in which construction of Phase 1 is anticipated to begin in early 2022 and be completed 10 months later; construction of Phase 2 is expected to begin *immediately* following the completion of Phase 1 construction and be completed 10 months later. Section 2.3.13 - Buildout Horizon of the EIR states that "For the purposes of providing a conservative, worst-case scenario, this Draft EIR assumes that Phases 1 and 2 would be developed concurrently over a period of 18 months." The EIR must be revised to utilize immediate construction and operation of both phases of development in order to be internally consistent and provide an adequate and accurate environmental analysis. Utilizing "incremental" construction of the project's buildings serves to artificially skew the growth-inducing impacts of the project downward. This analysis is erroneous and the EIR must be revised and recirculated for public review. 7c

7.0 Effects Found not to be Significant

7.2.9 Population and Housing

The EIR does not provide any analysis of the project's impacts to population and housing. The only discussion refers the reader to Section 6.2 - Growth Inducing Impacts. The EIR states that the project will employ "an estimated 1,200 workers during construction and 3,643 workers when fully operational at buildout." However, the EIR does not provide a methodology or source of calculation that was utilized to determine the project would generate 1,200 construction jobs and 3,643 operational jobs. The EIR must be revised to include the methodology for employment generation in order to comply with CEQA's requirements for meaningful disclosure. 8a

Further, the EIR relies upon the combined Napa-Solano labor force of 273,500 people to conclude that "the local labor force is sufficiently large enough to allow the project's employment 8b

opportunities to be filled locally such that unplanned growth would not occur." However, the EIR has not provided any meaningful evidence to support this conclusion. The size of labor market does not equate to number of available workers, number of workers qualified work in the industrial sector, or number of workers interested in work in the industrial sector. Relying upon the entire labor force of Napa and Solano Counties greatly exceeds the 16.24 miles of VMT per employee utilized by the Transportation analysis to determine the project will not have a significant impact 8b

on VMT. Napa County is 789 square miles in area and Solano County is 906 square miles in area. Relying on the entire labor force of Napa and Solano Counties to fill the project's construction and operational jobs will increase VMT and emissions during all phases of construction and operations and the EIR must be revised to account for longer worker trip distances.

The EIR does not discuss the project's compliance with the Association of Bay Area Governments (ABAG) RTP/SCS (Plan Bay Area 2050). Plan Bay Area 2050's Growth Pattern[11] notes that the South Napa County area (Napa City and American Canyon City combined) will add 19,000 jobs between 2015 - 2050. Utilizing the EIR's calculation of 3,643 employees, the project represents 19% of South Napa County's employment growth from 2015 - 2050. Plan Bay Area 2050's Growth Pattern notes that the South Napa County's population will increase by 5,000 residents between 2015 - 2050. Utilizing the EIR's calculation of 3,643 employees, the project represents 72% of South Napa County's population growth from 2015 - 2050. A single project accounting for this amount of the projected employment and/or population over 35 years represents a significant amount of growth. The EIR must be revised to include this analysis, and also provide a cumulative analysis discussion of projects approved since 2015 and projects "in the pipeline" in American Canyon and City of Napa to determine if the project will exceed Plan Bay Area 2050's employment and/or population growth forecast for South Napa County. Additionally, the EIR must also provide demographic and geographic information on the location of qualified workers to fill these positions in order to provide an accurate environmental analysis. 8c

Conclusion

For the foregoing reasons, GSEJA believes the EIR is flawed and a revised EIR must be prepared for the proposed project and circulated for public review. Golden State Environmental Justice Alliance requests to be added to the public interest list regarding any subsequent environmental 9

Subject: Comments on the Giovannoni Logistics Center Project (SCH No. 2021010104)

Dear Mr. Ho,

We have reviewed the May 2022 Draft Environmental Impact Report ("DEIR") for the Giovannoni Logistics Center Project ("Project") located in the City of American Canyon ("City"). The Project proposes the development of up to 2,400,000-square-feet ("SF") of high-cube warehouse space on the 208-acre site throughout two phases. Phase 1 proposes to construct two high-cube warehouse buildings totaling 1,069,904-SF and 860 parking spaces on a 94.7-acre site, while Phase 2 conceptually proposes to construct the remaining 1,300,000-SF of high-cube warehouse space on a 113.1-acre site after Phase 1 is completed. 1

Our review concludes that the DEIR fails to adequately evaluate the Project's air quality and health risk impacts. As a result, emissions and health risk impacts associated with construction and operation of the proposed Project are underestimated and inadequately addressed. An updated EIR should be prepared to adequately assess and mitigate the potential air quality and health risk impacts that the project may have on the environment.

Air Quality

Failure to Implement All Feasible Mitigation to Reduce Emissions

The DEIR concludes that the Project would result in a significant-and-unavoidable operational air quality impact. Specifically, the DEIR estimates that the ROG and NO_x emissions associated with operation of both the Dry Storage and Cold Storage Project Scenarios would exceed the applicable Bay Area Air Quality Management District ("BAAQMD") annual threshold of 10 tons per year ("tons/year"), as well as the BAAQMD daily threshold of 54 pounds per day ("lbs/day") (see excerpt below) (p. 3.2-52 – 3.2-54, Table 3.2-13). 2a

Table 3.2-13: Mitigated Operational Emissions

lb. = pounds ROG = reactive organic gases NO_x = oxides of nitrogen
PM_{10} = particulate matter 10 microns in diameter$PM_{2.5}$ = particulate matter 2.5 microns in diameter
ND = No Data
Source: CalEEMod Output (see Appendix B).

2a

As a result, the DEIR concludes that the impacts associated with Project operation would be significant-and-unavoidable (p. 3.2-59). However, while we agree that the Project's criteria air pollutant emissions would result in a significant air quality impact, the DEIR's conclusion that these impacts are "significant and unavoidable" is incorrect. According to CEQA Guidelines § 15096(g)(2):

> "When an EIR has been prepared for a project, the Responsible Agency shall not approve the project as proposed if the agency finds any feasible alternative or feasible mitigation measures within its powers that would substantially lessen or avoid any significant effect the project would have on the environment."

As stated above, an impact can only be labeled as significant and unavoidable after all available, feasible mitigation is considered. Here, while the DEIR includes Mitigation Measure ("MM") AQ-2a through AQ-2d, the DEIR fails to implement *all* feasible mitigation (p. 3.2-58 – 3.2-59). Therefore, the DEIR's conclusion that the Project's air quality impacts are significant-and-unavoidable is unsubstantiated. To reduce the Project's air quality impacts to the maximum extent possible, additional feasible mitigation measures should be incorporated, such as those suggested in the section of this letter titled "Feasible Mitigation Measures Available to Reduce Emissions." Thus, the Project should not be approved until an updated EIR is prepared, incorporating all feasible mitigation to reduce emissions to less-than-significant levels. 2a

Unsubstantiated Input Parameters Used to Estimate Project Emissions

The DEIR's air quality analysis relies on emissions calculated with the California Emissions Estimator Model ("CalEEMod") Version 2020.4.0 (p. 3.2-1).[1] CalEEMod provides recommended default values based on site-specific information, such as land use type, meteorological data, total lot acreage, project type and typical equipment associated with project type. If more specific project information is known, the user can change the default values and input project-specific values, but the California Environmental Quality Act ("CEQA") requires that such changes be justified by substantial evidence. Once all of the values are inputted into the model, the Project's construction and operational emissions are calculated, and "output files" are generated. These output files disclose to the reader what parameters are utilized in calculating the Project's air pollutant emissions and make known which default values are changed as well as provide justification for the values selected. 2b

When reviewing the Project's CalEEMod output files, provided in the Air Quality, Energy, Greenhouse Gas Supporting Information ("AQ & GHG Analysis") as Appendix B to the DEIR, we found that the following model input is not consistent with information disclosed in the DEIR. As a result, the Project's operational emissions are underestimated. An updated EIR should be prepared to include an updated air quality analysis that adequately evaluates the impacts that Project operation will have on local and regional air quality.

Failure to Model Operational Daily Truck Trips

The AQ & GHG Analysis provides the Giovannoni Logistics Project CalEEMod Notes ("CalEEMod Notes") to justify and provide additional explanation regarding the changes to the default values included in the Project's air models. Specifically, regarding the Project's expected number of operational vehicle trips and associated trip lengths, CalEEMod Note #9 states: 2c

[1] "CalEEMod Version 2020.4.0." California Air Pollution Control Officers Association (CAPCOA), May 2021, *available at:* https://www.aqmd.gov/caleemod/download-model.

> "W-Trans prepared a Traffic Impact Study (TIS) for the proposed project that analyzes the trip generation rates for the proposed project. The TIS illustrates that at full buildout (Phases 1 and 2), the proposed project would generate an estimated 528 daily truck trips and 2,832 daily passenger vehicle trips. According to the TIS, passenger vehicles would travel an average of 16.24 VMT per person per day. As this VMT would represent all travel to and from the project site for employees, an average of 8.12 miles per vehicle trip was utilized in this analysis. According to correspondence with the Project Applicant, the anticipated port of product origin for truck trips would be the Port of Oakland, approximately 32.8 miles away. Therefore, trip distances and trip generation rates were adjusted in the project operation models to reflect this information" (p. 3).

As demonstrated above, the proposed Project expects to generate 528 daily truck trips (with a trip length of approximately 32.8 miles) and 2,832 daily passenger car trips (with a trip length of approximately 8.12 miles). Furthermore, regarding the Project's expected passenger car and truck fleet mix percentages, CalEEMod Note #9 continues, stating:

> "According to telephone correspondence with the Project Applicant, trucks to serve the project upon operation are anticipated to have an average gross vehicle weight rating (GVWR) of 35,000 pounds. Therefore, the fleet mix for the proposed project was adjusted to reflect 100 percent of truck trips as classified under the Heavy Heavy-Duty (HHD) vehicle class and 100 percent of passenger vehicle trips as classified under the Light-Duty Auto (LDA), Light-Duty Truck Type 1 (LDT1), Light-Duty Truck Type 2 (LDT2), and Medium-Duty Vehicle (MDV) vehicle classes, according to their respective fleet proportions found in the California Air Resources Board's (ARB) EMFAC2017 database for the first year of full buildout (2023). Please refer to the Fleet Mix Adjustment sheet found in this Appendix for more information" (p. 3).

2c

As demonstrated above, the Project's truck fleet mix was adjusted to be 100% Heavy Heavy-Duty ("HHD") vehicles, while the Project's passenger car fleet mix was adjusted to be a mixture of Light-Duty Auto ("LDA"), Light-Duty Truck Type 1 ("LDT1"), Light-Duty Truck Type 2 ("LDT2"), and Medium-Duty Vehicle ("MDV") vehicles.

Review of the CalEEMod output files demonstrates that the operational models include a total of 2,832 daily operational vehicle trips (see excerpts below) (Appendix B, pp. 101, 109, 117, 126, 154, 166, 176, 186, 215, 226, 236, 246).[2]

[2] Calculated: (1,263.66 Phase 1 vehicle trips) + (1,568.34 Phase 2 vehicle trips) = 2,832 total vehicle trips.

Phase 1 models: "Giovanni Logistics Phase 1 DRY Op," "Giovanni Logistics Phase 1 COLD Op," "Giovannoni Logistics Phase 1 COLD Op – AIR-2c," "Giovannoni Logistics Phase 1 DRY Op – AIR-2c," "Giovannoni Logistics Phase 1 COLD 2030 Op – AIR-2c," and "Giovannoni Logistics Phase 1 DRY 2030 Op – AIR-2c"

	Average Daily Trip Rate		
Land Use	Weekday	Saturday	Sunday
City Park	0.00	0.00	0.00
Parking Lot	0.00	0.00	0.00
Refrigerated Warehouse-No Rail	554.03	554.03	554.03
Refrigerated Warehouse-Rail	709.63	709.63	709.63
Total	1,263.66	1,263.66	1,263.66

Phase 2 models: "Giovannoni Logistics Phase 2 COLD Op," "Giovannoni Logistics Phase 2 DRY Op," "Giovannoni Logistics Phase 2 COLD Op - AIR-2c," "Giovannoni Logistics Phase 2 DRY Op - AIR-2c," "Giovanni Logistics Phase 2 COLD 2030 Op - AIR-2c," and "Giovannoni Logistics Phase 2 DRY 2030 Op - AIR-2c"

	Average Daily Trip Rate		
Land Use	Weekday	Saturday	Sunday
City Park	0.00	0.00	0.00
Parking Lot	0.00	0.00	0.00
Refrigerated Warehouse-Rail	1,568.34	1,568.34	1568.34
Total	1,568.34	1,568.34	1,568.34

2c

Furthermore, all of the 2,832 vehicle trips are modeled with a trip length of 8.12 miles and fleet mix accounting for Light-Duty Auto ("LDA"), Light-Duty Truck Type 1 ("LDT1"), Light-Duty Truck Type 2 ("LDT2"), and Medium-Duty Vehicle ("MDV") vehicles (see excerpts below) (Appendix B, pp. 101, 109, 117, 126, 154, 166, 176, 186, 215, 226, 236, 246).

Phase 1 models: "Giovanni Logistics Phase 1 DRY Op," "Giovanni Logistics Phase 1 COLD Op," "Giovannoni Logistics Phase 1 COLD Op – AIR-2c," "Giovannoni Logistics Phase 1 DRY Op – AIR-2c," "Giovannoni Logistics Phase 1 COLD 2030 Op – AIR-2c," and "Giovannoni Logistics Phase 1 DRY 2030 Op – AIR-2c"

	Miles			Trip %

2c

As demonstrated in the excerpts above, all 2,832 operational vehicle trips included in the models reflect passenger car trips, consistent with the information provided by the CalEEMod Notes. ***However, the operational models fail to include the proposed 528 daily truck trips.***

This presents an issue, as CalEEMod uses the operational vehicle trips to calculate the emissions associated with the operational on-road vehicles.[3] Furthermore, trucks are a major source of diesel particulate matter ("DPM") emissions, which have health effects including cardiovascular and respiratory hospitalizations, as well as premature death.[4] Thus, by failing to include the proposed daily truck trips, the models underestimate the Project's mobile-source operational emissions and potential health risk impacts, and should not be relied upon to determine Project significance.

Diesel Particulate Matter Health Risk Emissions Inadequately Evaluated

The DEIR concludes that the proposed Project would result in a less-than-significant health risk impact based on a quantified construction and operational health risk assessment ("HRA"). Specifically, the DEIR estimates that the maximum incremental cancer risk posed to nearby, existing residential sensitive receptors associated with exposure to diesel particulate matter ("DPM") emissions during Project construction and operation would be 2.10 in one million, which would not exceed the BAAQMD significance threshold of 10 in one million (see excerpt below) (p. 3.2-60 – 3.2-61, Table 3.2-14).

Table 3.2-14: Summary of Construction Health Risks at the Maximum Impacted Receptor

Impact Scenario	Cancer Risk[1] (risk per million)	Chronic Non-Cancer Hazard Index[2]	TAC Concentration[3] (µg/m³)
Residential MIR Impact (Cold Storage Scenario)			
Scenario 1 (Phase 1 Construction)	0.44	<0.01	<0.01
Scenario 2 (Phase 2 Construction, Phase 1 Operation)	1.44	<0.01	0.01
Scenario 3 (Phase 1, Phase 2 Operation)	0.22	0.01	0.04
Total (30 Year Duration)	*2.10*	*0.01*	*0.05*
Thresholds of Significance	**10**	**1**	**0.3**
Exceeds Individual Source Threshold?	**No**	**No**	**No**
School MIR Impact (Cold Storage Scenario)			
Scenario 1 (Phase 1 Construction)	0.01	<0.01	<0.01
Scenario 2 (Phase 2 Construction, Phase 1 Operation)	0.03	<0.01	<0.01
Scenario 3 (Phase 1, Phase 2 Operation)	<0.20	<0.01	<0.01
Total (30 Year Duration)	*0.24*	*<0.01*	*<0.01*
Thresholds of Significance	**10**	**1**	**0.3**
Exceeds Individual Source Threshold?	**No**	**No**	**No**

Notes:
$PM_{2.5}$ = particulate matter, including dust, 2.5 micrometers or less in diameter
REL = reference exposure level DPM = diesel particulate matter TAC = toxic air contaminants
MIR = Maximally Impacted Sensitive Receptor µg/m³ = micrograms per cubic meter
[1] Cancer risk is identified by multiplying the risk sum from HARP2 by 1,000,000.
[2] Chronic non-cancer hazard index was estimated by dividing the annual DPM concentration (as $PM_{2.5}$ exhaust) by the DPM REL of 5 µg/m³.
[3] TAC concentration taken from AERMOD is always at the MIR identified from the project air dispersion models. The residential MIR was located at 38.20613°N -122.25739°E and the school MIR was identified as the Calvary Baptist Christian Academy.
Emissions Source: Appendix B.
Thresholds Source: Bay Area Air Quality Management District (BAAQMD). 2017. California Environmental Quality Act Air Quality Guidelines. May. Website: https://www.baaqmd.gov/~/media/files/planning-and-research/ceqa/ceqa_guidelines_may2017-pdf.pdf?la=en. Accessed April 15, 2021.

2d

However, the DEIR's evaluation of the Project's potential health risk impacts, as well as the subsequent less-than-significant impact conclusion, is incorrect for two reasons.

First, the DEIR's HRA is incorrect, as it relies upon emissions estimates from a flawed air model (see excerpt below) (p. 3.2-61, Table 3.2-14).

Notes:
$PM_{2.5}$ = particulate matter, including dust, 2.5 micrometers or less in diameter
REL = reference exposure level DPM = diesel particulate matter TAC = toxic air contaminants
MIR = Maximally Impacted Sensitive Receptor µg/m³ = micrograms per cubic meter
[1] Cancer risk is identified by multiplying the risk sum from HARP2 by 1,000,000.
[2] Chronic non-cancer hazard index was estimated by dividing the annual DPM concentration (as $PM_{2.5}$ exhaust) by the DPM REL of 5 µg/m³.
[3] TAC concentration taken from AERMOD is always at the MIR identified from the project air dispersion models. The residential MIR was located at 38.20613°N -122.25739°E and the school MIR was identified as the Calvary Baptist Christian Academy.
Emissions Source: Appendix B.
Thresholds Source: Bay Area Air Quality Management District (BAAQMD). 2017. California Environmental Quality Act Air Quality Guidelines. May. Website: https://www.baaqmd.gov/~/media/files/planning-and-research/ceqa/ceqa_guidelines_may2017-pdf.pdf?la=en. Accessed April 15, 2021.

As previously discussed, when we reviewed the Project's CalEEMod output files, provided in the AQ & GHG Analysis as Appendix B to the DEIR, we found that the model fails to include the Project's expected number of daily truck trips. This poses a significant problem, as trucks emit high levels of diesel exhaust that the Project's air modeling does not account for. As such, the HRA utilizes an underestimated DPM concentration to calculate the health risk associated with Project construction and operation. As such, the DEIR's HRA and resulting cancer risk are underestimated and should not be relied upon to determine Project significance. 2d

Second, the DEIR's HRA is unsubstantiated, as the DEIR fails to provide the input parameters and modeling assumptions. Specifically, upon review of the HRA, we found that the exposure parameters, such as the daily breathing rates ("BR/BW"), exposure duration ("ED"), age sensitivity factors ("ASF"), fraction of time at home ("FAH"), and exposure frequency ("EF") are not disclosed. As such, we cannot verify the calculation of the Project's cancer risk is accurate. As a result, the Project's cancer risk may be underestimated and should not be relied upon to determine Project significance.

Mitigation

Feasible Mitigation Measures Available to Reduce Emissions

Our analysis demonstrates that the Project results in significant operational air quality impacts that should be mitigated further. As such, in an effort to reduce the Project's emissions, we identified several mitigation measures that are applicable to the proposed Project. Feasible mitigation measures can be found in the Department of Justice Warehouse Project Best Practices document.[5] Therefore, to reduce the Project's emissions, consideration of the following measures should be made: 2e

- Prohibiting off-road diesel-powered equipment from being in the "on" position for more than 10 hours per day.
- Forbidding idling of heavy equipment for more than two minutes.
- Keeping onsite and furnishing to the lead agency or other regulators upon request, all equipment maintenance records and data sheets, including design specifications and emission control tier classifications.

[5] "Warehouse Projects: Best Practices and Mitigation Measures to Comply with the California Environmental Quality Act." State of California Department of Justice.

- Using paints, architectural coatings, and industrial maintenance coatings that have volatile organic compound levels of less than 10 g/L.
- Providing information on transit and ridesharing programs and services to construction employees.
- Providing meal options onsite or shuttles between the facility and nearby meal destinations for construction employees.
- Requiring that all facility-owned and operated fleet equipment with a gross vehicle weight rating greater than 14,000 pounds accessing the site meet or exceed 2010 model-year emissions equivalent engine standards as currently defined in California Code of Regulations Title 13, Division 3, Chapter 1, Article 4.5, Section 2025. Facility operators shall maintain records on-site demonstrating compliance with this requirement and shall make records available for inspection by the local jurisdiction, air district, and state upon request.
- Requiring all heavy-duty vehicles entering or operated on the project site to be zero-emission beginning in 2030.
- Requiring on-site equipment, such as forklifts and yard trucks, to be electric with the necessary electrical charging stations provided.
- Requiring tenants to use zero-emission light- and medium-duty vehicles as part of business operations.
- Forbidding trucks from idling for more than two minutes and requiring operators to turn off engines when not in use.
- Posting both interior- and exterior-facing signs, including signs directed at all dock and delivery areas, identifying idling restrictions and contact information to report violations to CARB, the air district, and the building manager. 2e
- Installing and maintaining, at the manufacturer's recommended maintenance intervals, air filtration systems at sensitive receptors within a certain radius of facility for the life of the project.
- Installing and maintaining, at the manufacturer's recommended maintenance intervals, an air monitoring station proximate to sensitive receptors and the facility for the life of the project, and making the resulting data publicly available in real time. While air monitoring does not mitigate the air quality or greenhouse gas impacts of a facility, it nonetheless benefits the affected community by providing information that can be used to improve air quality or avoid exposure to unhealthy air.
- Constructing electric truck charging stations proportional to the number of dock doors at the project.
- Constructing electric plugs for electric transport refrigeration units at every dock door, if the warehouse use could include refrigeration.
- Constructing electric light-duty vehicle charging stations proportional to the number of parking spaces at the project.
- Installing solar photovoltaic systems on the project site of a specified electrical generation capacity, such as equal to the building's projected energy needs.
- Requiring all stand-by emergency generators to be powered by a non-diesel fuel.

- Requiring facility operators to train managers and employees on efficient scheduling and load management to eliminate unnecessary queuing and idling of trucks.
- Requiring operators to establish and promote a rideshare program that discourages single-occupancy vehicle trips and provides financial incentives for alternate modes of transportation, including carpooling, public transit, and biking.
- Meeting CalGreen Tier 2 green building standards, including all provisions related to designated parking for clean air vehicles, electric vehicle charging, and bicycle parking.
- Achieving certification of compliance with LEED green building standards.
- Providing meal options onsite or shuttles between the facility and nearby meal destinations.
- Posting signs at every truck exit driveway providing directional information to the truck route.
- Improving and maintaining vegetation and tree canopy for residents in and around the project area.
- Requiring that every tenant train its staff in charge of keeping vehicle records in diesel technologies and compliance with CARB regulations, by attending CARB approved courses. Also require facility operators to maintain records on-site demonstrating compliance and make records available for inspection by the local jurisdiction, air district, and state upon request. 2e
- Requiring tenants to enroll in the United States Environmental Protection Agency's SmartWay program, and requiring tenants to use carriers that are SmartWay carriers.
- Providing tenants with information on incentive programs, such as the Carl Moyer Program and Voucher Incentive Program, to upgrade their fleets.

These measures offer a cost-effective, feasible way to incorporate lower-emitting design features into the proposed Project, which subsequently, reduce emissions released during Project operation. An updated EIR should be prepared to include all feasible mitigation measures, as well as include an updated air quality analysis to ensure that the necessary mitigation measures are implemented to reduce emissions to below thresholds. The updated EIR should also demonstrate a commitment to the implementation of these measures prior to Project approval, to ensure that the Project's significant emissions are reduced to the maximum extent possible.

Disclaimer

SWAPE has received limited discovery regarding this project. Additional information may become available in the future; thus, we retain the right to revise or amend this report when additional information becomes available. Our professional services have been performed using that degree of care and skill ordinarily exercised, under similar circumstances, by reputable environmental consultants practicing in this or similar localities at the time of service. No other warranty, expressed or implied, is made as to the scope of work, work methodologies and protocols, site conditions, analytical testing results, and findings presented. This report reflects efforts which were limited to information that was reasonably accessible at the time of the work, and may contain informational gaps, inconsistencies, or otherwise be incomplete due to the unavailability or uncertainty of information obtained or provided by third parties. 3

Sincerely,

Matt Hagemann, P.G., C.Hg.

Matthew F. Hagemann, P.G., C.Hg., QSD, QSP

Geologic and Hydrogeologic Characterization
Investigation and Remediation Strategies
Litigation Support and Testifying Expert
Industrial Stormwater Compliance
CEQA Review

Education:

M.S. Degree, Geology, California State University Los Angeles, Los Angeles, CA, 1984.
B.A. Degree, Geology, Humboldt State University, Arcata, CA, 1982.

Professional Certifications:

California Professional Geologist
California Certified Hydrogeologist
Qualified SWPPP Developer and Practitioner

Professional Experience:

Matt has 30 years of experience in environmental policy, contaminant assessment and remediation, stormwater compliance, and CEQA review. He spent nine years with the U.S. EPA in the RCRA and Superfund programs and served as EPA's Senior Science Policy Advisor in the Western Regional Office where he identified emerging threats to groundwater from perchlorate and MTBE. While with EPA, Matt also served as a Senior Hydrogeologist in the oversight of the assessment of seven major military facilities undergoing base closure. He led numerous enforcement actions under provisions of the Resource Conservation and Recovery Act (RCRA) and directed efforts to improve hydrogeologic characterization and water quality monitoring. For the past 15 years, as a founding partner with SWAPE, Matt has developed extensive client relationships and has managed complex projects that include consultation as an expert witness and a regulatory specialist, and a manager of projects ranging from industrial stormwater compliance to CEQA review of impacts from hazardous waste, air quality and greenhouse gas emissions.

Positions Matt has held include:

- Founding Partner, Soil/Water/Air Protection Enterprise (SWAPE) (2003 – present);
- Geology Instructor, Golden West College, 2010 – 2104, 2017;
- Senior Environmental Analyst, Komex H2O Science, Inc. (2000 -- 2003);

4

- Executive Director, Orange Coast Watch (2001 – 2004);
- Senior Science Policy Advisor and Hydrogeologist, U.S. Environmental Protection Agency (1989–1998);
- Hydrogeologist, National Park Service, Water Resources Division (1998 – 2000);
- Adjunct Faculty Member, San Francisco State University, Department of Geosciences (1993 – 1998);
- Instructor, College of Marin, Department of Science (1990 – 1995);
- Geologist, U.S. Forest Service (1986 – 1998); and
- Geologist, Dames & Moore (1984 – 1986).

Senior Regulatory and Litigation Support Analyst:

With SWAPE, Matt's responsibilities have included:

- Lead analyst and testifying expert in the review of over 300 environmental impact reports and negative declarations since 2003 under CEQA that identify significant issues with regard to hazardous waste, water resources, water quality, air quality, greenhouse gas emissions, and geologic hazards. Make recommendations for additional mitigation measures to lead agencies at the local and county level to include additional characterization of health risks and implementation of protective measures to reduce worker exposure to hazards from toxins and Valley Fever.
- Stormwater analysis, sampling and best management practice evaluation at more than 100 industrial facilities.
- Expert witness on numerous cases including, for example, perfluorooctanoic acid (PFOA) contamination of groundwater, MTBE litigation, air toxins at hazards at a school, CERCLA compliance in assessment and remediation, and industrial stormwater contamination.
- Technical assistance and litigation support for vapor intrusion concerns.
- Lead analyst and testifying expert in the review of environmental issues in license applications for large solar power plants before the California Energy Commission.
- Manager of a project to evaluate numerous formerly used military sites in the western U.S.
- Manager of a comprehensive evaluation of potential sources of perchlorate contamination in Southern California drinking water wells.
- Manager and designated expert for litigation support under provisions of Proposition 65 in the review of releases of gasoline to sources drinking water at major refineries and hundreds of gas stations throughout California.

4

With Komex H2O Science Inc., Matt's duties included the following:

- Senior author of a report on the extent of perchlorate contamination that was used in testimony by the former U.S. EPA Administrator and General Counsel.
- Senior researcher in the development of a comprehensive, electronically interactive chronology of MTBE use, research, and regulation.
- Senior researcher in the development of a comprehensive, electronically interactive chronology of perchlorate use, research, and regulation.
- Senior researcher in a study that estimates nationwide costs for MTBE remediation and drinking water treatment, results of which were published in newspapers nationwide and in testimony against provisions of an energy bill that would limit liability for oil companies.
- Research to support litigation to restore drinking water supplies that have been contaminated by MTBE in California and New York.

- Expert witness testimony in a case of oil production-related contamination in Mississippi.
- Lead author for a multi-volume remedial investigation report for an operating school in Los Angeles that met strict regulatory requirements and rigorous deadlines.
- Development of strategic approaches for cleanup of contaminated sites in consultation with clients and regulators.

Executive Director:

As Executive Director with Orange Coast Watch, Matt led efforts to restore water quality at Orange County beaches from multiple sources of contamination including urban runoff and the discharge of wastewater. In reporting to a Board of Directors that included representatives from leading Orange County universities and businesses, Matt prepared issue papers in the areas of treatment and disinfection of wastewater and control of the discharge of grease to sewer systems. Matt actively participated in the development of countywide water quality permits for the control of urban runoff and permits for the discharge of wastewater. Matt worked with other nonprofits to protect and restore water quality, including Surfrider, Natural Resources Defense Council and Orange County CoastKeeper as well as with business institutions including the Orange County Business Council.

Hydrogeology:

As a Senior Hydrogeologist with the U.S. Environmental Protection Agency, Matt led investigations to characterize and cleanup closing military bases, including Mare Island Naval Shipyard, Hunters Point Naval Shipyard, Treasure Island Naval Station, Alameda Naval Station, Moffett Field, Mather Army Airfield, and Sacramento Army Depot. Specific activities were as follows: 4

- Led efforts to model groundwater flow and contaminant transport, ensured adequacy of monitoring networks, and assessed cleanup alternatives for contaminated sediment, soil, and groundwater.
- Initiated a regional program for evaluation of groundwater sampling practices and laboratory analysis at military bases.
- Identified emerging issues, wrote technical guidance, and assisted in policy and regulation development through work on four national U.S. EPA workgroups, including the Superfund Groundwater Technical Forum and the Federal Facilities Forum.

At the request of the State of Hawaii, Matt developed a methodology to determine the vulnerability of groundwater to contamination on the islands of Maui and Oahu. He used analytical models and a GIS to show zones of vulnerability, and the results were adopted and published by the State of Hawaii and County of Maui.

As a hydrogeologist with the EPA Groundwater Protection Section, Matt worked with provisions of the Safe Drinking Water Act and NEPA to prevent drinking water contamination. Specific activities included the following:

- Received an EPA Bronze Medal for his contribution to the development of national guidance for the protection of drinking water.
- Managed the Sole Source Aquifer Program and protected the drinking water of two communities through designation under the Safe Drinking Water Act. He prepared geologic reports, conducted

public hearings, and responded to public comments from residents who were very concerned about the impact of designation.
- Reviewed a number of Environmental Impact Statements for planned major developments, including large hazardous and solid waste disposal facilities, mine reclamation, and water transfer.

Matt served as a hydrogeologist with the RCRA Hazardous Waste program. Duties were as follows:
- Supervised the hydrogeologic investigation of hazardous waste sites to determine compliance with Subtitle C requirements.
- Reviewed and wrote "part B" permits for the disposal of hazardous waste.
- Conducted RCRA Corrective Action investigations of waste sites and led inspections that formed the basis for significant enforcement actions that were developed in close coordination with U.S. EPA legal counsel.
- Wrote contract specifications and supervised contractor's investigations of waste sites.

With the National Park Service, Matt directed service-wide investigations of contaminant sources to prevent degradation of water quality, including the following tasks:
- Applied pertinent laws and regulations including CERCLA, RCRA, NEPA, NRDA, and the Clean Water Act to control military, mining, and landfill contaminants.
- Conducted watershed-scale investigations of contaminants at parks, including Yellowstone and Olympic National Park.
- Identified high-levels of perchlorate in soil adjacent to a national park in New Mexico and advised park superintendent on appropriate response actions under CERCLA.
- Served as a Park Service representative on the Interagency Perchlorate Steering Committee, a national workgroup.
- Developed a program to conduct environmental compliance audits of all National Parks while serving on a national workgroup.
- Co-authored two papers on the potential for water contamination from the operation of personal watercraft and snowmobiles, these papers serving as the basis for the development of nation-wide policy on the use of these vehicles in National Parks.
- Contributed to the Federal Multi-Agency Source Water Agreement under the Clean Water Action Plan.

4

Policy:

Served senior management as the Senior Science Policy Advisor with the U.S. Environmental Protection Agency, Region 9.

Activities included the following:
- Advised the Regional Administrator and senior management on emerging issues such as the potential for the gasoline additive MTBE and ammonium perchlorate to contaminate drinking water supplies.
- Shaped EPA's national response to these threats by serving on workgroups and by contributing to guidance, including the Office of Research and Development publication, Oxygenates in Water: Critical Information and Research Needs.
- Improved the technical training of EPA's scientific and engineering staff.
- Earned an EPA Bronze Medal for representing the region's 300 scientists and engineers in negotiations with the Administrator and senior management to better integrate scientific

principles into the policy-making process.
- Established national protocol for the peer review of scientific documents.

Geology:

With the U.S. Forest Service, Matt led investigations to determine hillslope stability of areas proposed for timber harvest in the central Oregon Coast Range. Specific activities were as follows:

- Mapped geology in the field, and used aerial photographic interpretation and mathematical models to determine slope stability.
- Coordinated his research with community members who were concerned with natural resource protection.
- Characterized the geology of an aquifer that serves as the sole source of drinking water for the city of Medford, Oregon.

As a consultant with Dames and Moore, Matt led geologic investigations of two contaminated sites (later listed on the Superfund NPL) in the Portland, Oregon, area and a large hazardous waste site in eastern Oregon. Duties included the following:

- Supervised year-long effort for soil and groundwater sampling.
- Conducted aquifer tests.
- Investigated active faults beneath sites proposed for hazardous waste disposal.

Teaching:

From 1990 to 1998, Matt taught at least one course per semester at the community college and university levels:

- At San Francisco State University, held an adjunct faculty position and taught courses in environmental geology, oceanography (lab and lecture), hydrogeology, and groundwater contamination.
- Served as a committee member for graduate and undergraduate students.
- Taught courses in environmental geology and oceanography at the College of Marin.

Matt is currently a part time geology instructor at Golden West College in Huntington Beach, California where he taught from 2010 to 2014 and in 2017.

Paul Rosenfeld, Ph.D.

Chemical Fate and Transport & Air Dispersion Modeling

Principal Environmental Chemist

Risk Assessment & Remediation Specialist

Education

Ph.D. Soil Chemistry, University of Washington, 1999. Dissertation on volatile organic compound filtration.

M.S. Environmental Science, U.C. Berkeley, 1995. Thesis on organic waste economics.

B.A. Environmental Studies, U.C. Santa Barbara, 1991. Thesis on wastewater treatment.

Professional Experience

Dr. Rosenfeld has over 25 years' experience conducting environmental investigations and risk assessments for evaluating impacts to human health, property, and ecological receptors. His expertise focuses on the fate and transport of environmental contaminants, human health risk, exposure assessment, and ecological restoration. Dr. Rosenfeld has evaluated and modeled emissions from oil spills, landfills, boilers and incinerators, process stacks, storage tanks, confined animal feeding operations, industrial, military and agricultural sources, unconventional oil drilling operations, and locomotive and construction engines. His project experience ranges from monitoring and modeling of pollution sources to evaluating impacts of pollution on workers at industrial facilities and residents in surrounding communities. Dr. Rosenfeld has also successfully modeled exposure to contaminants distributed by water systems and via vapor intrusion.

Dr. Rosenfeld has investigated and designed remediation programs and risk assessments for contaminated sites containing lead, heavy metals, mold, bacteria, particulate matter, petroleum hydrocarbons, chlorinated solvents, pesticides, radioactive waste, dioxins and furans, semi- and volatile organic compounds, PCBs, PAHs, creosote, perchlorate, asbestos, per- and poly-fluoroalkyl substances (PFOA/PFOS), unusual polymers, fuel oxygenates (MTBE), among other pollutants. Dr. Rosenfeld also has experience evaluating greenhouse gas emissions from various projects and is an expert on the assessment of odors from industrial and agricultural sites, as well as the evaluation of odor nuisance impacts and technologies for abatement of odorous emissions. As a principal scientist at SWAPE, Dr. Rosenfeld directs air dispersion modeling and exposure assessments. He has served as an expert witness and testified about pollution sources causing nuisance and/or personal injury at sites and has testified as an expert witness on numerous cases involving exposure to soil, water and air contaminants from industrial, railroad, agricultural, and military sources.

5

Professional History:

Soil Water Air Protection Enterprise (SWAPE); 2003 to present; Principal and Founding Partner
UCLA School of Public Health; 2007 to 2011; Lecturer (Assistant Researcher)
UCLA School of Public Health; 2003 to 2006; Adjunct Professor
UCLA Environmental Science and Engineering Program; 2002-2004; Doctoral Intern Coordinator
UCLA Institute of the Environment, 2001-2002; Research Associate
Komex H_2O Science, 2001 to 2003; Senior Remediation Scientist
National Groundwater Association, 2002-2004; Lecturer
San Diego State University, 1999-2001; Adjunct Professor
Anteon Corp., San Diego, 2000-2001; Remediation Project Manager
Ogden (now Amec), San Diego, 2000-2000; Remediation Project Manager
Bechtel, San Diego, California, 1999 – 2000; Risk Assessor
King County, Seattle, 1996 – 1999; Scientist
James River Corp., Washington, 1995-96; Scientist
Big Creek Lumber, Davenport, California, 1995; Scientist
Plumas Corp., California and USFS, Tahoe 1993-1995; Scientist
Peace Corps and World Wildlife Fund, St. Kitts, West Indies, 1991-1993; Scientist

Teaching Experience:

UCLA Department of Environmental Health (Summer 2003 through 20010) Taught Environmental Health Science 100 to students, including undergrad, medical doctors, public health professionals and nurses. Course focused on the health effects of environmental contaminants.

National Ground Water Association, Successful Remediation Technologies. Custom Course in Sante Fe, New Mexico. May 21, 2002. Focused on fate and transport of fuel contaminants associated with underground storage tanks.

National Ground Water Association; Successful Remediation Technologies Course in Chicago Illinois. April 1, 2002. Focused on fate and transport of contaminants associated with Superfund and RCRA sites.

California Integrated Waste Management Board, April and May, 2001. Alternative Landfill Caps Seminar in San Diego, Ventura, and San Francisco. Focused on both prescriptive and innovative landfill cover design.

UCLA Department of Environmental Engineering, February 5, 2002. Seminar on Successful Remediation Technologies focusing on Groundwater Remediation. 5

University Of Washington, Soil Science Program, Teaching Assistant for several courses including: Soil Chemistry, Organic Soil Amendments, and Soil Stability.

U.C. Berkeley, Environmental Science Program Teaching Assistant for Environmental Science 10.

Academic Grants Awarded:

California Integrated Waste Management Board. $41,000 grant awarded to UCLA Institute of the Environment. Goal: To investigate effect of high carbon wood ash on volatile organic emissions from compost. 2001.

Synagro Technologies, Corona California: $10,000 grant awarded to San Diego State University.
Goal: investigate effect of biosolids for restoration and remediation of degraded coastal sage soils. 2000.

King County, Department of Research and Technology, Washington State. $100,000 grant awarded to University of Washington: Goal: To investigate odor emissions from biosolids application and the effect of polymers and ash on VOC emissions. 1998.

Northwest Biosolids Management Association, Washington State. $20,000 grant awarded to investigate effect of polymers and ash on VOC emissions from biosolids. 1997.

James River Corporation, Oregon: $10,000 grant was awarded to investigate the success of genetically engineered Poplar trees with resistance to round-up. 1996.

United State Forest Service, Tahoe National Forest: $15,000 grant was awarded to investigating fire ecology of the Tahoe National Forest. 1995.

Kellogg Foundation, Washington D.C. $500 grant was awarded to construct a large anaerobic digester on St. Kitts in West Indies. 1993

Deposition and/or Trial Testimony:

In the Circuit Court Of The Twentieth Judicial Circuit, St Clair County, Illinois
Martha Custer et al., Plaintiff vs. Cerro Flow Products, Inc., Defendants
Case No.: No. 0i9-L-2295
Rosenfeld Deposition, 5-14-2021
Trial, October 8-4-2021

In the Circuit Court of Cook County Illinois
Joseph Rafferty, Plaintiff vs. Consolidated Rail Corporation and National Railroad Passenger Corporation d/b/a AMTRAK,
Case No.: No. 18-L-6845
Rosenfeld Deposition, 6-28-2021

In the United States District Court For the Northern District of Illinois
Theresa Romcoe, Plaintiff vs. Northeast Illinois Regional Commuter Railroad Corporation d/b/a METRA Rail, Defendants
Case No.: No. 17-cv-8517
Rosenfeld Deposition, 5-25-2021

In the Superior Court of the State of Arizona In and For the Cunty of Maricopa
Mary Tryon et al., Plaintiff vs. The City of Pheonix v. Cox Cactus Farm, L.L.C., Utah Shelter Systems, Inc.
Case Number CV20127-094749
Rosenfeld Deposition: 5-7-2021

In the United States District Court for the Eastern District of Texas Beaumont Division
Robinson, Jeremy et al *Plaintiffs*, vs. CNA Insurance Company et al.
Case Number 1:17-cv-000508
Rosenfeld Deposition: 3-25-2021

In the Superior Court of the State of California, County of San Bernardino
Gary Garner, Personal Representative for the Estate of Melvin Garner vs. BNSF Railway Company.
Case No. 1720288
Rosenfeld Deposition 2-23-2021

In the Superior Court of the State of California, County of Los Angeles, Spring Street Courthouse
Benny M Rodriguez vs. Union Pacific Railroad, A Corporation, et al.
Case No. 18STCV01162
Rosenfeld Deposition 12-23-2020

In the Circuit Court of Jackson County, Missouri
Karen Cornwell, *Plaintiff,* vs. Marathon Petroleum, LP, *Defendant.*
Case No.: 1716-CV10006
Rosenfeld Deposition. 8-30-2019

In the United States District Court For The District of New Jersey
Duarte et al, *Plaintiffs,* vs. United States Metals Refining Company et. al. *Defendant.*
Case No.: 2:17-cv-01624-ES-SCM
Rosenfeld Deposition. 6-7-2019

5

In the United States District Court of Southern District of Texas Galveston Division
M/T Carla Maersk, *Plaintiffs,* vs. Conti 168., Schiffahrts-GMBH & Co. Bulker KG MS "Conti Perdido" *Defendant.*
Case No.: 3:15-CV-00106 consolidated with 3:15-CV-00237
Rosenfeld Deposition. 5-9-2019

In The Superior Court of the State of California In And For The County Of Los Angeles – Santa Monica
Carole-Taddeo-Bates et al., vs. Ifran Khan et al., Defendants
Case No.: No. BC615636
Rosenfeld Deposition, 1-26-2019

In The Superior Court of the State of California In And For The County Of Los Angeles – Santa Monica
The San Gabriel Valley Council of Governments et al. vs El Adobe Apts. Inc. et al., Defendants
Case No.: No. BC646857
Rosenfeld Deposition, 10-6-2018; Trial 3-7-19

In United States District Court For The District of Colorado
Bells et al. Plaintiff vs. The 3M Company et al., Defendants
Case No.: 1:16-cv-02531-RBJ
Rosenfeld Deposition, 3-15-2018 and 4-3-2018

In The District Court Of Regan County, Texas, 112th Judicial District
Phillip Bales et al., Plaintiff vs. Dow Agrosciences, LLC, et al., Defendants
Cause No.: 1923
Rosenfeld Deposition, 11-17-2017

In The Superior Court of the State of California In And For The County Of Contra Costa
Simons et al., Plaintiffs vs. Chevron Corporation, et al., Defendants
Cause No C12-01481
Rosenfeld Deposition, 11-20-2017

In The Circuit Court Of The Twentieth Judicial Circuit, St Clair County, Illinois
Martha Custer et al., Plaintiff vs. Cerro Flow Products, Inc., Defendants
Case No.: No. 0i9-L-2295
Rosenfeld Deposition, 8-23-2017

In United States District Court For The Southern District of Mississippi
Guy Manuel vs. The BP Exploration et al., Defendants
Case: No 1:19-cv-00315-RHW
Rosenfeld Deposition, 4-22-2020

In The Superior Court of the State of California, For The County of Los Angeles
Warrn Gilbert and Penny Gilber, Plaintiff vs. BMW of North America LLC
Case No.: LC102019 (c/w BC582154)
Rosenfeld Deposition, 8-16-2017, Trail 8-28-2018

In the Northern District Court of Mississippi, Greenville Division
Brenda J. Cooper, et al., *Plaintiffs,* vs. Meritor Inc., et al., *Defendants*
Case Number: 4:16-cv-52-DMB-JVM
Rosenfeld Deposition: July 2017

Organizations

Note to Reader: This letter includes the attachment from SWAPE

Golden State Environmental Justice Alliance (GSEJA)

Note to reader: GSEJA submitted a letter with an attachment prepared by SWAPE. Each organization's comments will be addressed separately.

Response to GSEJA-1
The organization provided introductory remarks and summarized the project. No environmental issues related to the proposed project were identified in this comment and no further response is necessary.

Response to GSEJA-2a
The organization opined the Draft EIR does not include relevant environmental justice issues for analysis in review of potential impacts from the proposed project. The organization notes this is significant given that communities surrounding the proposed project are more polluted than average on several pollution indicators measured by CalEnviroScreen.

Nothing in CEQA requires EIRs to consider environmental justice as part of the environmental impact analysis required under CEQA. CEQA Guidelines Section 15360 defines "the environment" as "the *physical conditions* which exist within the area which will be affected by a proposed project including land, air, water, minerals, flora, fauna, ambient noise, and objects of historical or aesthetic significance." (Italics added.) These components of the physical environment are represented in the categories of environmental impacts included within the sample initial study checklist found in Appendix G to the CEQA Guidelines. That checklist does not include any questions focused on "environmental justice."

Effects that are solely social or economic in nature do not constitute an effect on the physical environment. Neither the California Air Resources Board (ARB) nor the Bay Area Air Quality Management District (BAAQMD) have recommended significance thresholds adjusted for environmental justice considerations; therefore, the Draft EIR utilized the currently recommended BAAQMD significance thresholds to determine health risk impacts resulting from the proposed project. The Draft EIR evaluated potential impacts to the local community in Section 3.2, Air Quality, through the analysis of cumulatively considerable criteria pollutant emissions and health risks under Impacts AIR-2 and AIR-3. The project site is near the existing sensitive receptors the organization mentions, and the Draft EIR identifies the cumulative health impacts that would occur from project construction and operation combined with existing permitted stationary sources, local roadway traffic, freeway traffic, and rail traffic.

Response to GSEJA-2b
The organization generally describes the environmental and health impacts of hazardous waste and toxic releases on surrounding communities. The organization points out the proposed project's census tract ranks 84th percentile for solid waste facility impacts, 61st percentile for toxic releases, and 83rd percentile for hazardous waste impacts.

No project-specific comments were provided and, thus, no further response is required.

Response to GSEJA-2c
The organization generally describes the racial, economic, educational demographics of the proposed project's census tract. The comment states that due to high incidences of cardiovascular disease and asthma in this census tract, access to medical care is vital.

No project-specific comments were provided and, thus, no further response is required.

Response to GSEJA-2d
The organization stated the Draft EIR did not accurately or adequately model the energy impacts of the proposed project in compliance with Title 24 and a finding of significance must be made. The organization recommends circulating a revised EIR in which one of the State of California approved energy compliance modeling software for nonresidential buildings (CBECC-Com, EnergyPro, or IES VE), rather than CalEEMod, is used.

The Draft EIR's air quality analysis utilized an approved emissions estimating model in CalEEMod based on the BAAQMD guidance. The comment's assertion regarding use of the CalEEMod is incorrect. The BAAQMD identifies CalEEMod as a CEQA resource that can be used to assess air quality and its impact on communities and public health. The use of CBECC-Com, EnergyPro, and IES VE are not recommended for CEQA analyses within the BAAQMD and would not be appropriate to estimate greenhouse gas (GHG) emissions or energy impacts. The Draft EIR accurately and adequately modeled energy impacts in compliance with Title 24. The lead agency's decision-makers will review the entire Final EIR and other documents in the administrative record prior to making findings regarding the decision to certify the Final EIR and render a decision on the proposed project.

Response to GSEJA-2e
The organization states the Draft EIR's Transportation analysis does not consider medium and heavy-duty trucks in its VMT analysis. The organization notes the operation of the proposed project would involve high rates of medium and heavy-duty truck/trailer VMT and thus recommends a revised EIR be prepared to reflect these factors in the VMT analysis. The organization states a revised VMT analysis must be used to revise the GHG analysis to determine whether the project-generated VMT is 15 percent below the prescribed threshold.

VMT is addressed in Master Response 4.

Response to GSEJA-2f
The organization stated that relying on the combined workforce of Napa and Solano County to fill the proposed project's operational jobs would increase VMT and GHG emissions during construction and operation of the proposed project and exceeds the 26.24 miles of VMT per employee used by the Transportation Analysis to determine the proposed project's impact on VMT. The organization recommends the GHG analysis be revised to account for longer work trip distances.

VMT is addressed in Master Response 4. See Response to Comment GSEJA-8b for a discussion of the likely pool of workers for the proposed project.

The comment does not raise any issues that require a revision of the Draft EIR.

Response to GSEJA-3a
The organization alleged that Draft EIR, Section 3.9, Land Use, Table 3.9-2, provided a misleading consistency analysis with the City of American Canyon General Plan. The agency cited the consistency analysis with Land Use Element Objective 1.2 and claimed it is inconsistent with the Development Capacity Table on Land Use Element Page 1-12.

The Draft EIR introduced Table 3.9-2, on pages 3.9-6 and 3.9-7, by stating:

> "[t]he conclusions expressed in Table 3. 9-2 reflect the best judgment of City staff. The ultimate question of the meaning of particular General Plan policies, and thus the proposed project' s consistency with them, lies with the City Council. The language found in general plans is sometimes susceptible to varying interpretations. Case law interpreting the Planning and Zoning Law (Government Code, § 65000 *et seq*.) makes it clear that: (i) the ultimate meaning of such policies is to be determined by the elected city council or a lower tier decision- making body such as a planning commission, as opposed to city staff and EIR consultants, applicants, or members of the public; and (ii) the decision- making body' s interpretations of such policies will prevail if they are "reasonable," even though other reasonable interpretations are also possible (See *No Oil, Inc. v. City of Los Angeles* (1987) 196 Cal.App.3d 223, 245-246, 249). Courts also have recognized that, because general plans often contain numerous policies adopted to effect differing or competing legislative goals, a development project may be "consistent" with a general plan, taken as a whole, even though the project appears to be inconsistent or arguably inconsistent with some specific policies within a given general plan (*Sequoyah Hills Homeowners Association v. City of Oakland* (1993) 23 Cal.App.4th 704, 719). Furthermore, courts strive to "reconcile" or harmonize" seemingly disparate general plan policies to the extent reasonably possible (*No Oil*, *supra*, 196 Cal.App.3d at p. 244)."

As these principles make clear, reasonable minds may differ with respect to both the meaning of a particular General Plan policy and whether a proposed project is or is not consistent with such a policy. Thus, GSEJA may sincerely believe the proposed project is inconsistent with certain General Plan objectives and policies. But its opinions are in no way binding on City decision-makers, which have broad discretion to reach different conclusions.

The draft EIR's Objective 1.2 consistency analysis provides a through and comprehensive review of General Plan policies, goals and objectives and is reproduced and discussed below:

Objective 1.2	Promote a rate of growth that is consistent with the ability of the City to provide adequate infrastructure and services and does not adversely impact the distinctive character and quality of life in American Canyon.	**Consistent:** The proposed project would develop 2.4 million square feet of new industrial uses on a site designated for such use located within the American Canyon city limits. The project site is located within the Green Island Business Park and is surrounded by urban uses and infrastructure on three sides. Thus, the proposed project would occur in an area where adequate infrastructure and services exist such that it would not exceed the City's ability to serve it.

The Draft EIR's consistency analysis identifies how the project (1) would develop high-cube warehouse uses on a site designated Industrial by the General Plan; (2) would be compatible with surrounding land uses; and (3) is located in an area served with adequate infrastructure. Moreover, Objective 1.2 makes no reference to the Development Capacity Table on Land Use Element Page 1-12. Hence, there is no basis to assess Objectively 1.2 using the Development Capacity Table.

The Development Capacity Table is further addressed in Response to GSEJA-3d.

Response to GSEJA-3b
The organization alleged the consistency analysis with Economic Development Element Objective 3.4 and claimed it is inconsistent with the objective because the Draft EIR identifies a significant unavoidable impact associated with air quality.

The Draft EIR's Objective 3.4 consistency analysis is reproduced and discussed below:

Objective 3.4	Increase the number of firms within the industries now represented in the City and capture new, clean, nonpolluting industries that are stable and compatible with City needs in terms of traffic, air quality, and employment.	**Consistent:** The proposed project would develop 2.4 million square feet of high-cube warehouse on an approximately 208-acre site in the Green Island Business Park. These types of uses currently exist within the Airport Industrial Area. Additionally, the proposed project is estimated to create 3,643 new jobs. The proposed project would implement traffic improvements to mitigate for impacts on traffic operations.

Economic Development Element Objective 3.4 expresses the City's general desire to attract new businesses to the City that minimize traffic and air quality impacts while also providing stable employment opportunities and land use compatibility. The Draft EIR's consistency analysis identifies how the project (1) would create new jobs; (2) represents the continued development of the Green Island Business Park; (3) is compatible with the Napa County Airport; and (4) would implement traffic improvements. Objective 3.4 is silent about what CEQA conclusions are acceptable in order to achieve consistency with this objective. Moreover, both Napa Logistics Park Phase II and Napa

Airport Corporate Center were found consistent with Objective 3.4 for the same reasons as Giovannoni Logistics Center despite also having significant unavoidable air quality impacts. Thus, the City has established a precedent for interpretation of Objective 3.4. Hence, there is no basis to evaluate project consistency with Objective 3.4 based on CEQA conclusions. Notably, a local general plan policy that precluded all industrial development with even one significant unavoidable effect would likely frustrate the local government's economic development objectives, as such significant unavoidable effects are very common, particularly in air basins that are not in attainment for all pollutants regulated under federal and State air quality laws. The question whether a particular industry is "clean" and "nonpolluting" is a relative one. Certainly, logistics centers are clean and nonpolluting in comparison with traditional heavy industries involving, for example, petroleum refining or chemical manufacturing.

Response to GSEJA-3c

The organization alleged the consistency analysis with Circulation Element Policy 1.11 is inconsistent with the policy because of the omission of medium and heavy-duty trucks from the VMT analysis.

The Draft EIR's Guiding Policy 1.11 consistency analysis is reproduced and discussed below:

Guiding Policy 1.11	Reduce Vehicle Miles Traveled. Through layout of land uses, improved alternate modes, and provision of more direct routes, strive to reduce the total vehicle miles traveled by City residents.	**Consistent:** The project site is located within the Napa County Airport Industrial Area, which has convenient access to SR-12 and SR-29. The development of the proposed project's 2.4 million square feet of high-cube warehouse is within the North Bay Region and would contribute to reducing trip length by locating these facilities closer to customers within this region. Finally, the development of up to 3,643 new jobs in a housing-rich part of the Bay Area region would allow employees to work closer to where they live, thereby reducing vehicle miles traveled.

Guiding Policy 1.11 expresses a general desire to reduce VMT through various planning techniques. The Draft EIR's consistency analysis identifies proximity to regional highways and residential uses as project attributes consistent with Guiding Policy 1.11. Moreover, Guiding Policy 1.11 is silent how a CEQA VMT analysis would inform a consistency finding, much less the methodology of such an analysis. Hence, there is no basis to use the conclusions of a CEQA VMT analysis as the basis for assessing consistency with Guiding Policy 1.11.

The organization's specific comments about the Draft EIR's VMT analysis, including the contention the analysis is deficient for failing to account for medium- and heavy-duty truck traffic, are addressed in Response to GSEJA-4a through GSEJA-4d, as well as Master Response 4.

Response to GSEJA-3d

The organization alleged the Draft EIR omitted a consistency analysis with Land Use Policy 1.3.4's Development Capacity Table, which identifies up to 5,778,500 square feet of additional industrial development provided the circulation improvements in the General Plan are implemented.

No EIR can be legally inadequate for failing to address a proposed project's consistency with a General Plan policy with which the project is *consistent*. Rather, CEQA Guidelines Section 15125, subdivision (d), requires that "[t]he EIR shall discuss any *in*consistencies between the proposed project and applicable general plans, specific plans, and regional plans." (Italics added; see also, *City of Long Beach v. Los Angeles Unified School Dist.* (2009) 176 Cal.App.4th 889, 918-919 [EIRs need not address policies with which proposed projects are consistent].)

City staff concludes the proposed project is consistent with the Development Capacity Table found in Land Use Policy 1.3.4, the introductory text of which states the City should "[l]imit the total additional new development that can be accommodated in the City and its Urban Limit to the following *provided that the highway improvements stipulated by the Circulation Element are implemented*." (Italics added.) One key term in that policy is "additional new development." The Land Use Element is silent as to what is the baseline value that the additional new development can be compared to. Underscoring this issue, the California Department of Finance indicates the City of American Canyon has 5,050 single-family dwelling units as of January 1, 2022, which exceeds the total value of 4,882 in the Development Capacity Table.

Another key element of Land Use Policy 1.3.4 is the obvious linkage between "additional new development" and "highway improvements stipulated by the Circulation Element[.]" This linkage shows the additional new development beyond the levels shown in the table following Policy 1.3.4 would be allowed provided highway improvements at issue were implemented. Thus, new development should not get out ahead of transportation infrastructure needed to support it.

Hence, it is clear the City never intended Development Capacity Table to be used as a hard and fast limit on General Plan buildout but rather intended the table to inform how much growth can occur until all of the contemplated circulation improvements were put in place.

This understanding of Land Use Policy 1.3.4 and its capacity table is evident from past land use and development decisions made by the City of American Canyon. The City annexed a substantial amount of acreage in the northern portion of the City in 2005 (including the Giovannoni property), thereby increasing buildout potential for nonresidential uses. The City completed the first segment of the Devlin Road extension from South Kelly Road to Napa Logistics Park in 2012, enabling this area to be developed. The City subsequently approved Napa Logistics Park Phase 2 in 2015, Napa Airport Corporate Center in 2018, and the Broadway District Specific Plan in 2019. Also, the City approved the Watson Ranch Specific Plan in 2019, which includes an extension of Newell Drive. The annexation, approval, or development of all of these projects suggests that the Development Capacity Table was never intended to be interpreted as a hard limit on growth.

Furthermore, the General Plan makes clear elsewhere the project site is within the (1) city limits and (2) is designated for "Industrial" use. Thus, when one considers to the totality of all Land Use

Element goals, objectives, and policies that pertain to growth management, it is clear the City's intention is to prioritize development of infill sites within the city limits served with existing infrastructure. Moreover, completion of Devlin Road between Green Island Road and Middleton Way is a General Plan-identified circulation improvement that provides a parallel route to SR-29 improves circulation in the project vicinity.

In sum, GSEJA's suggestion that the Development Capacity Table represents a hard cap on new development in American Canyon is inconsistent with the plain language of the policy, the General Plan's policy direction viewed as a whole, and the manner in which City decision-makers have historically interpreted Land Use Policy 1.3.4.

Response to GSEJA-3e
The organization alleged the Draft EIR omitted a consistency analysis with Land Use Goal 1T, which calls for the establishment of an Urban Limit Line through January 1, 2030.

Goal 1T applies to the American Canyon policy makers (i.e., the City Council) and not individual development projects. Regardless, as shown on the General Plan Land Use Map, the project site is within both the American Canyon city limits and Urban Limit Line.

Response to GSEJA-3f
The organization alleged the Draft EIR omitted a consistency analysis with Land Use Policy 1.22.9, which requires permitting and regulation of industrial land uses that handle hazardous materials.

The City of American Canyon General Plan allows a range of end users within the Industrial land use category, many of which do not handle large quantities of hazardous materials. Regardless, because no end users have been identified, it would be speculative to further discuss a potential end users consistency with Policy 1.22.9.

Furthermore, the Draft EIR evaluated hazardous materials impacts in Section 3.7, Hazards and Hazardous Materials, and found all impacts would be less than significant and did not require mitigation.

Response to GSEJA-3g
The organization alleged the Draft EIR omitted a consistency analysis with Economic Development Element Objective 3.2, which calls for growth that generates net positive fiscal impacts for the City.

Fiscal impacts are outside the scope of environmental review because they do not have physical impacts on the environment. Nothing in CEQA requires the City to consider the proposed project's consistency with this objective. (See, CEQA Guidelines, § 15131, subd. (a) ["[e]conomic or social effects of a project shall not be treated as significant effects on the environment"]).

Response to GSEJA-3h
The organization alleged the Draft EIR omitted a consistency analysis with Economic Development Policy 3.2.1, which calls for a fiscal impact analysis for certain types of projects.

Fiscal impacts are outside the scope of environmental review because they do not have physical impacts on the environment. Regardless, a fiscal impact analysis, entitled American Canyon

Giovannoni Logistics Center Fire Services Fiscal Analysis and prepared by Economic and Planning Systems, Inc. dated May 6, 2022, was prepared in accordance with this policy. This analysis is included as Appendix K of this Final EIR.

Response to GSEJA-3i
The organization alleged the proposed project is inconsistent with the General Plan's goals, objectives, and policies due to aforementioned comments about significant unavoidable air quality impacts and VMT.

Refer to Responses to GSEJA-3b and GSEJA-3c.

Response to GSEJA-3j
The organization reiterated prior comments about the proposed project's inconsistency with the Development Capacity Table.

Please refer to Response to GSEJA-3d for a discussion regarding potential industrial development. As detailed in the Draft EIR and these responses to comments, the proposed project would not be inconsistent with the General Plan and no revisions or recirculation of the Draft EIR is required.

Response to GSEJA-4a
The organization alleged the VMT analysis omitted medium- and heavy-duty truck trips from the VMT analysis and, thus, it does not accurately reflect all project-related VMT.

VMT is addressed in Master Response 4.

Response to GSEJA-4b
The organization alleged the Statewide Travel Demand Model utilized in the VMT analysis was cited as a technical reference but not incorporated by reference pursuant to CEQA Guidelines Section 15150, subdivision (f). Therefore, the City was not required, under subdivision (b) of that section, to make the data available to the public for inspection at a public place or public building.

VMT is addressed in Master Response 4.

Response to GSEJA-4c
The organization referenced the VMT per employee number of 16.24 miles and alleged it was in conflict with a statement in the growth inducement analysis that the project labor force would come from Napa and Solano Counties.

Refer to Response to GSEJA-8b.

Response to GSEJA-4d
The organization alleged the Draft EIR's VMT analysis referenced policies used by the Governor's Office of Planning and Research (OPR), Sacramento County, and the City of San José but failed to incorporate them by reference in the Draft EIR.

The Draft EIR complies with CEQA's requirements for technical detail and citation of information outlined in CEQA Guidelines Sections 15147 and 15148. Incorporation by reference is not required, or appropriate for all documents. See Section 15150(f). VMT is addressed in Master Response 4.

Response to GSEJA-5a
The organization alleged the Draft EIR's Cumulative Effects analysis did not account for the Development Capacity Table and reiterated prior comments about the project's square footage exceeding that allowed by the table.

As indicated in Response to GSEJA-3d, the organization's interpretation of the Development Capacity Table materially differs from how the City of American Canyon interprets the table. Thus, there is no deficiency with the cumulative effects analysis as it relates to the Development Capacity Table. As is evident from Draft EIR, Section 4, Cumulative Effects, Table 4-1, Cumulative Projects, page 4-1 and in the cumulative analysis that follows, the City primarily relied on the so-called "list method" for identifying probable future projects that would create impacts that would compound those of past and present projects, along with the proposed project itself. This method is authorized by CEQA Guidelines Section 15130, subdivision (b)(1)(A). Table 4-1 includes probable future projects that are either awaiting approval, approved but not yet constructed, or under construction. This approach fully satisfied CEQA. Nothing in the law required the City to use the Development Capacity Table from General Plan Land Use Policy 1.3.4 as the basis for conducting cumulative impact analysis.

Response to GSEJA-5b
The organization alleged the Draft EIR's Cumulative Effects analysis did not discuss the Association of Bay Area Government (ABAG) Plan Bay Area growth projections for South Napa County. The organization claimed the proposed project's 3,643 employees would represent 19 percent of South Napa County's employment growth between 2015 and 2050. The organization noted that 3,643 employees would represent 72 percent of South Napa County population growth between 2015-2050.

As indicated in Response to GSEJA-7b, the organization's claims about project consistency with Plan Bay Area growth projections are not supported by substantial evidence. Thus, there is no deficiency with the cumulative effects analysis as it relates to Plan Bay Area growth projections. As noted in the Response to GSEJA-5a, the City primarily relied on the so-called "list method" authorized by CEQA Guidelines Section 15130, subdivision (b)(1)(A), for identifying probable future projects that would create impacts that would compound those of past and present projects, along with the proposed project itself. In doing so, the City fully complied with applicable CEQA requirements.

Response to GSEJA-6
The organization alleged the Draft EIR's Alternative's analysis failed to evaluate a reasonable range of alternatives that meet the project objectives and eliminates all proposed project's significant and unavoidable impacts. The organization asserted the Draft EIR must be revised to include such an alternative.

"There is no ironclad rule governing the nature or scope of alternatives to be discussed other than the rule of reason." (CEQA Guidelines, § 15126.6, subd. (a), citing *Citizens of Goleta Valley v. Board of Supervisors* (1990) 52 Cal.3d 553 and *Laurel Heights Improvement Association v. Regents of the*

University of California (1988) 47 Cal.3d 376).) "An EIR need not consider every conceivable alternative to a project. Rather it must consider a reasonable range of potentially feasible alternatives that will foster informed decision-making and public participation." (CEQA Guidelines, § 15126.6, subd. (a); see also *Mount Shasta Bioregional Ecology Center v. County of Siskiyou* (2012) 210 Cal.App.4th 184, 196 [same].) A court must uphold an agency's selection of alternatives "unless the challenger demonstrates that the alternatives are manifestly unreasonable and that they do not contribute to a reasonable range of alternatives." (*Cal. Native Plant Society v. City of Santa Cruz* (2009) 177 Cal.App.4th 957, 988.)

Here, the Draft EIR includes a reasonable range of alternatives that need not be supplemented by additional alternatives to be legally adequate. The Draft EIR evaluated four alternatives in detail (No Project/No Development, No Project/Existing General Plan, Reduced Density, and Phase 1 Only) and considered two alternatives initially considered but ultimately rejected from further consideration (Phase 2 Only and Alternative Location). By any objective standard, this is clearly a "reasonable range" of alternatives, particularly given the characteristics of the proposed project.

As for the organization's suggestion the Draft EIR must be revised to identify an alternative that meets all of the project objectives and eliminates all of the significant unavoidable impacts, this is not required by the CEQA Guidelines. Rather, CEQA Guidelines Section 15126.6 requires evaluation of alternatives "which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project." In this case, the Phase 1 Only Alternative was identified as the Environmentally Superior Alternative because it met the most project objectives while achieving the greatest reduction in the severity of project impacts.

Response to GSEJA-7a

The organization referenced the growth inducement analysis in Chapter 6, Other CEQA Considerations, and noted it does not reference the General Plan Land Use Element's Development Capacity Table. The organization reiterated previous comments about the lack of analysis of this issue.

As discussed on Draft EIR Chapter 6, Other CEQA Considerations, pages 6-1 and 6-2, growth inducement concerns facilitating substantial direct or indirect growth (e.g., new housing or new employment opportunities) or removal of a physical barrier to growth (e.g., extension of sewer into an unserved area). In the case of the proposed project, it is entirely nonresidential and located within an area served by urban infrastructure. The analysis explained the proposed project would employ an estimated 1,200 workers during construction and 3,643 workers when fully operational at buildout, but would likely be built incrementally over a period of years, with the result that jobs would be added in blocks as the project builds out. Thus, there would not be an "overnight" influx of new employment opportunities. The analysis also noted that in October 2021 the California Employment Development Department estimated the combined Napa- Solano labor force at 273,500, making the local labor force is sufficiently large to allow the project' s employment opportunities to be filled locally. Nor would the proposed project require construction of additional housing in American Canyon to shelter its workers. As the Draft EIR explained, the City of American Canyon has more than 2,400 dwelling units in the pipeline. For comparison purposes, American Canyon' s population was estimated to be 20,837. The addition of more than 2,400 dwelling units to

the City' s housing inventory would more than offset the employment growth attributable to the proposed project. Furthermore, the proposed project would pay the City's Affordable Housing Nexus Fee (Ordinance 2016-05) which funds affordable housing projects generated by the need for additional housing caused by new employment.

In sum, the Draft EIR's analysis appropriately focused on the potential for the proposed project's new employment opportunities to cause unplanned growth. No such unplanned growth will occur. Nor will the local housing market be strained. Regardless, the Development Capacity Table would provide no insight into any of these issues and, thus, the Draft EIR appropriately did not reference it.

Refer to Response to GSEJA-3d for further discussion of the Development Capacity Table.

Response to GSEJA-7b
The organization stated the growth inducement analysis in Chapter 6, Other CEQA Considerations, did not address the cumulative growth impacts and noted the proposed project's 3,643 employees would represent 19 percent of South Napa County's employment growth between 2015 and 2050. The organization noted that 3,643 employees would represent 72 percent of South Napa County population growth between 2015-2050.

The proposed project is the single largest industrial project in terms of square footage in American Canyon history. For its buildout employment to represent 19 percent of South Napa County's employment growth between 2015 and 2050 would not be unexpected nor represent an inconsistency with regional growth projections.

The organization's claim the proposed project's employment growth would correlate 1:1 to population growth in South Napa County is unsupported by evidence. No end users have been identified and no hiring has occurred. Thus, it is unknown where project employees reside. Given that American Canyon is within 10 miles of population centers in Solano County (e.g., Vallejo, Benicia, and Fairfield) that are not within the South Napa County subregion, project employees would have numerous options of places to live. For these reasons, the organization's claims in this regard are speculative.

Response to GSEJA-7c
The organization referenced a statement in growth inducement analysis in Chapter 6, Other CEQA Considerations, that the proposed project would "likely be built incremental over a period of years" and alleged it was inconsistent with how the air quality analysis evaluated buildout over a 20-month period. The organization asserted the Draft EIR must be revised to reconcile this inconsistency.

The Draft EIR's buildout assumptions are addressed in Master Response 3.

As for the statement in Chapter 6, Other CEQA Considerations, that the proposed project would "likely be built incremental over a period of years," is simply a statement to provide perspective to the reader regarding how buildout is anticipated to occur. Moreover, it is based on observations of actual buildout of neighboring Napa Logistics Park and Green Island Business Park. At the time of Final EIR publication, no end users had been identified, no resource agency permitting had been completed, and no design-level architectural plans or engineering studies had been completed for

project structures. All of these items can take months, if not years, to complete, which serves to reinforce the Draft EIR's basis that a 20-month buildout schedule is conservative. Regardless, the analysis in Chapter 6, Other CEQA Considerations, Section 6.2, Growth-Inducing Impacts, is based on whether the proposed project would result in direct or indirect growth-inducing impacts resulting, in part, from unplanned growth. The Draft EIR concludes the proposed project would be consistent with growth projections. Accordingly, even if the proposed project were to build out in 20 months, such a pace of development would not conflict with the conclusions of the growth inducement analysis.

Lastly, the statement in Draft EIR Chapter 2, Project Description, page 2-9 about "a period of 18 months" has been corrected to "a period of 20 to 24 months" and the change is noted in Final EIR Section 5, Errata. The change does not materially affect any conclusions of the air quality analysis since it used a 20-month buildout schedule.

Response to GSEJA-8a

The organization referenced discussion of population and housing in Draft EIR Section 7, Effects Found Not To Be Significant, and asserted the Draft EIR did not provide methodology for construction or operational employment estimates. The organization asserted the methodology must be disclosed.

The applicant submitted an Economic Impact Analysis prepared by Economic & Planning Systems, Inc. (EPS) to the City of American Canyon in December 2020. EPS estimated construction and buildout employment in Table 1, which were referenced in the Draft EIR in Chapter 2, Project Description on page 2-8, and Chapter 6, Other CEQA Consideration on page 6-1 and 6-2. The methodology used by EPS is described as follows:

Construction Employment

The referenced 1,200-job year figure was estimated using an Input/Output model using the IMPLAN software, which is a commonly used and industry standard application for this type of modeling. EPS used the estimated construction costs for the project as input for the Input/Output analysis.

This 1,200-job figure includes both direct (on-site) jobs and indirect (jobs at other businesses supported by construction). If the intention is to just capture on-site job years of project construction, the more relevant figure would be 1,030-job years shown on Table 2 of the Economic Impact Analysis as the direct effect. The additional 170 employees are at other businesses supporting the construction, such as local lumber or equipment suppliers.

Additionally, this figure represents job years and not necessarily employee estimates. If project construction lasts for more than a year, this number may double count some employee as one employee who is employed for 2 years would count as 2 job years.

Buildout Employment:

Similar to construction impacts, the 3,643-job estimate was estimated using the Input/Output model provided by IMPLAN. This estimate represents the total job economic impact of the proposed project, including direct, indirect, and induced employment as the economic activity from the

project ripples through the local economy. The proposed project itself is not anticipated to directly employ all these jobs on-site.

EPS estimated direct on-site employment at buildout of the project on Table A-1 of the Economic Impact Analysis by applying a standard 1,000 square feet per employee assumption (a commonly used assumption for projects of this type) to the total square footage of the proposed project to arrive at an on-site employment estimate of 2,399 employees. This was used as the input for the IMPLAN analysis.

On a broader note, the applicant's representative noted at the June 23, 2022, American Canyon Planning Commission Meeting (refer to Final EIR Section 4, Responses to June 23, 2022, Planning Commission Meeting Comments) that his firm has observed a trend of tenants consolidating separate, smaller spaces into single, larger spaces. Should this phenomenon play out at the proposed project, little to no change in overall net employment would occur.

In sum, it is possible the Draft EIR overestimated employment. However, more employment causes more impacts and, thus, even if 3,643 jobs overstates the actual buildout employment, it is consistent with providing a conservative analysis of reasonably foreseeable potential adverse impacts.

Response to GSEJA-8b

The organization referenced a statement in Draft EIR Chapter 6, Other CEQA Considerations, page 6-2 about the Napa-Solano labor force being sufficiently large enough to allow for the proposed project's employment opportunities to be filled locally and alleged that there is no meaningful evidence to support this conclusion. The organization alleged the size of the labor force does not equate to the number of available workers, the number of workers qualified to work in the industrial sector, or the number of workers interested in working in the industrial sector. The organization claimed that relying upon the entire labor force of Napa and Solano Counties greatly exceeds the 16.24 VMT per employee utilized in the Transportation analysis. The organization alleged that using the Napa-Solano labor force will increase VMT during all phases of construction and operations and, therefore, the Draft EIR must be revised to account for longer distances.

As previously noted in Response to GSEJA-7b, no end users have been identified and no hiring has occurred. Thus, it is unknown what types of qualifications would be required, who would be interested in the proposed project's employment opportunities, or where employees would reside. In the absence of this information, the Draft EIR used official State employment data to assess regional labor force characteristics at a macro level and determine whether the proposed project's employment opportunities could foreseeably cause substantial unplanned population growth. The Draft EIR noted the combined labor force of Napa and Solano Counties was 273,500 as of October 2021. The proposed project's estimated buildout employment of 3,643 would represent 1.3 percent of the October 2021 labor force estimate. The Draft EIR concluded the Napa-Solano labor force was sufficiently large to fill the jobs locally and, thus, substantial unplanned population growth would not occur. Without specific information about end users, any further analysis in this regard would be speculative. It is reasonable to assume, however, that very few workers would live in those areas of Napa and Solano Counties that are most distant from the project site. Rather, most workers are likely

to live within a reasonable commute distance. The commenter implies that the VMT calculations for the proposed project should assume appreciable numbers of workers would be traveling from the farthest reaches of the two counties. There is no evidentiary basis for such an assumption.

As previously noted in Response GSEJA-8a, it is possible the Draft EIR overestimated employment. Furthermore, as disclosed in the Draft EIR in Chapter 2, Project Description on page 2-9, and Chapter 6, Other CEQA Consideration on page 6-2, and 6-3, the buildout period may take years, if not decades. Thus, it would be expected that the Napa-Solano labor force would be substantially larger than 273,500 and even more capable of filling the proposed project's employment opportunities locally. Should either one of these things actually occur, it would reinforce the conservative, worst-case scenario nature of the analysis.

Lastly, the growth inducement analysis and VMT analysis employed separate methodologies. The growth inducement analysis as it relates to employment was based on the aforementioned regional assessment of the Napa-Solano labor force. The VMT analysis is based on a traffic model; refer to Draft EIR Section 3.12, Transportation, pages 3.12-16 and 3.12-17. Neither methodology relies upon the same data inputs nor is intended to address provide insight into both issues. Both analyses are conservative, though in different ways. Hence, attempting to commingle the conclusions misrepresents the analyses and the purposes for which they were prepared.

Regardless, the entire City of American Canyon and portions of the City of Napa, the City of Vallejo, and the City of Fairfield–the latter two are located in Solano County–are within 8 miles of the project site and, thus, the VMT per employee rate of 16.24 miles is readily attainable.

Response to GSEJA-8c

The organization alleged he Draft EIR did not discuss project consistency with ABAG's Regional Transportation Plan/Sustainable Communities Strategy (Plan Bay Area 2050). The organization reiterated previous comments about employment and population growth in the South Napa County subregion between 2015 and 2050. The organization reiterated prior comments about the Draft EIR omitting information about the location or qualifications of project employees.

The Draft EIR evaluated project consistency with the City of American Canyon General Plan in Impact LU-1 in Section 3.9, Land Use. The proposed project was found to be consistent with all applicable provisions of the General Plan. Plan Bay 2050 uses local land use plans as the basis for its regional population and employment projections; hence, the proposed project is implicitly consistent with Plan Bay Area 2050.

Refer to Response to GSEJA-7b through Response to GSEJA-8b for further discussion.

Response to GSEJA-9

The organization stated the Draft EIR is flawed and a revised EIR must be prepared.

As indicated in Responses to GSEJA-2a through GSEJA-8c, the organization's allegations of inadequate analysis are not supported by substantial evidence and, thus, there is no legal basis to revise and recirculate the Draft EIR.

Response to SWAPE-1
The organization provided introductory remarks and asserted the Draft EIR fails to adequately analyze the proposed project's air quality and health risk impacts.

As indicated in Responses to SWAPE-2a through SWAPE-2e, the organization's allegations of inadequate analysis are not supported by substantial evidence.

Response to SWAPE-2a
The organization states the Draft EIR fails to implement all feasible mitigation thus the conclusion the proposed project's air quality impacts are significant and unavoidable are unsubstantiated. The organization recommends a revised EIR be prepared that incorporates additional mitigation measures, such as those listed under "Feasible Mitigation Measures Available to Reduce Emissions."

The Draft EIR impact analysis is based on the City-approved Project Description and applicant provided site plans and information. This information was provided by architects, engineers, and planners with extensive knowledge of the proposed project and project operations. As described in Impact AIR-1, the Draft EIR considered project impacts in relation to the applicable Air Quality Plan (AQP), the BAAQMD 2017 Clean Air Plan. As described in Impact AIR-2, the Draft EIR considered the cumulative impact of criteria pollutant emissions from the proposed project. Furthermore, all potential mitigation measures were considered and ultimately, the mitigation measures included in the Draft EIR would be only measures that could feasibly be implemented by the City.

In addition, several of the measures recommended by the commenter are already incorporated into the analysis. For instance, MM AIR-2a, MM AIR-2b, and MM GHG-1a require the use of construction Best Management Plans (BMPs)—many are recommended by the BAAQMD—to reduce the generation of GHG emissions and fugitive dust during project construction, which correspond with the recommended measures for keeping construction equipment tuned to the manufacturer's specifications, limiting on-site equipment and vehicle idling times, and reducing the volatile organic compound (VOC) content of paints and coatings used during construction. Moreover, MM GHG-1c and MM GHG-1d require the proposed project to construct charging stations and construct the proposed buildings compliant with Tier 2 voluntary standards contained in the California Green Building Standards Code (CALGreen). These measures correspond to the commenter's recommendations for including electric truck charging stations, light-duty vehicle charging stations, plugs for electric Transport Refrigeration Units (TRUs), and a Tier 2 CALGreen energy efficiency building design. Finally, MM AIR-2d requires that trucks accessing the project site be model year 2014 or newer, which would achieve greater emission reductions than the commenter's recommendation for requiring trucks accessing the site to be model year 2010 or newer. The additional measures recommended by the commenter would not result in an appreciable reduction in project emissions or were determined not to be financially or technically feasible. As such, this comment is noted, and no additional measures have been identified that could practicably be included to result in project emissions sufficient to reduce impacts to less than significant. See Response to Comment SWAPE-2e below for a detailed assessment of each of the commenter's proposed mitigation measures.

Response to SWAPE-2b

The organization notes that CalEEMod provides recommended default values based on site-specific information, such as land use type, meteorological data, total lot acreage, project type and typical equipment associated with project type, and goes on to state that, if more specific project information is known, the user can change the default values and input project-specific values. The commenter adds that any such changes should be justified by substantial evidence. The organization contends that CalEEMod model input used in the Draft EIR is not consistent with information disclosed in the Draft EIR, thus the proposed project's operation emissions are underestimated. The organization recommends an updated Draft EIR be prepared to include an updated air quality analysis.

The technical inputs into the CalEEMod modeling reflect the best professional judgment of the air quality specialists at First Carbon Solutions who prepared the air quality analysis. This analysis was then reviewed by City of American Canyon planners with expertise in CEQA and environmental analysis. CalEEMod allows modelers to alter default assumptions in order to best reflect the circumstances and attributes of the particular projects being analyzed. That was done here based on input from the applicant, who will also serve as the construction contractor for the project. Although SWAPE might use different modeling inputs, the difference of opinion between SWAPE, on the one hand, and First Carbon Solutions and City staff, on the other, would not render the EIR inadequate. (CEQA Guidelines, § 15151.) The City of American Canyon was entitled to rely on the expert judgment of First Carbon Solutions and City planners, whose opinions and judgment constitute substantial evidence. (See, e.g., *Greenebaum v. City of Los Angeles* (1984) 153 Cal.App.3d 391, 413 [city decision-makers were entitled to rely on expert judgment of their planning staff; "[e]ven giving the appellants the benefit of the doubt and assuming that they may have had an expert compile and analyze their data for them, the fact that there are differing opinions arising from the same pool of information is not grounds for holding the EIR inadequate"].) As indicated in Response to SWAPE-2c, the organization's specific allegations of inadequate analysis are not supported by substantial evidence.

Response to SWAPE-2c

The commentator states the operational model included in the Draft EIR fails to include the proposed 528 daily truck trips, thus the models underestimate the proposed project's mobile-source operational emissions.

The commenter is incorrect in stating the air quality analysis failed to include 528 daily truck trips. As shown in *Draft EIR Appendix B* on page 3, and pages 8 through 29, emissions associated with trucking activity were calculated utilizing the ARB's EMission FACtors (EMFAC) *V*ersion 2017 for heavy-heavy-duty vehicle classes. EMFAC *V*ersion 2017 was utilized as it is consistent with the vehicle emission factors contained in CalEEMod *V*ersion 2020.4.0. Further, as identified in Section 3.2, Air Quality, and *Section* 3.6, Greenhouse Gas Emissions, the proposed project's emissions are delineated between area, energy, passenger vehicle, trucks, transport refrigerated units, water, and waste emission sources. As shown therein, the emissions associated with daily truck trips were considered in the Air Quality and Greenhouse Gas Emission analyses.

Response to SWAPE-2d

The organization stated the Draft EIR's evaluation of the proposed project's potential health risk impact, and the conclusion of a less than significant impact, is incorrect because it relies on emissions estimates from a flawed air model and the Draft EIR fails to provide the input parameters and modeling assumptions, including daily breathing rates, exposure duration, age sensitivity factors, fraction of time at home, and exposure frequency values. The organization says it is unable to verify the accuracy of the proposed project's cancer risk and asserts the cancer risk may be underestimated and should not be relied upon to determine project significance.

Please refer to Response to SWAPE-2c, which addresses inclusion of truck emissions in the emissions analysis. For the disclosure of daily breathing rates, exposure duration, age sensitivity factors, fraction of time at home, and exposure frequency values, a description of Health Risk Assessment (HRA) modeling inputs was provided in Appendix B to the Draft EIR, starting on page 329. As shown therein, the ARB's Hotspots Analysis and Reporting Program (HARP) was utilized for calculating the proposed project's potential health risk impacts. As disclosed on pages 332 and 333 of Appendix B, the HRA utilized the daily breathing rates, exposure duration, age sensitivity factors, fraction of time at home, and exposure frequency values recommended by the BAAQMD and lists out specific inputs utilized in HARP for residential and school receptors to correspond with those recommended values.

Response to SWAPE-2e

The organization stated the proposed project results in significant operational air quality impacts that should be mitigated further and provides several additional mitigation measures they request be added to the proposed project. The organization recommended an updated EIR be prepared to include all feasible mitigation measures, an updated air quality analysis, and a demonstrated commitment to implement these mitigation measures prior to project approval.

Table 3-1 below provides a feasibility analysis of each proposed mitigation measure. As indicated in the table, the proposed mitigation measures are (1) not necessary; (2) not feasible; (3) are already included as mitigation; or (4) have been included as new mitigation measures.

Table 3-1: Proposed Mitigation Measure Feasibility Analysis

Proposed Mitigation Measure	Analysis
Prohibiting off-road diesel powered equipment from being in the "on" position for more than 10 hours per day.	**Not Necessary:** Because construction criteria pollutant emissions are less than significant after mitigation, no further mitigation is necessary.
Forbidding idling of heavy equipment for more than 2 minutes.	**Not Necessary:** MM AIR-2a limits idling to no more than 5 minutes of idling in accordance with State law. Because construction criteria pollutant emissions are less than significant after mitigation, no further mitigation is necessary.
Keeping on-site and furnishing to the lead agency or other regulators upon request, all equipment maintenance records and data sheets, including design specifications and emission control tier classifications.	**Not Necessary:** Because construction criteria pollutant emissions are less than significant after mitigation, no further mitigation is necessary. Furthermore, mandating that records be made

Proposed Mitigation Measure	Analysis
	available for inspection by a government agency without a search warrant may be unlawful.
Using paints, architectural coatings, and industrial maintenance coatings that have volatile organic compound levels of less than 10 g/L.	**Not Necessary:** MM AIR-2b limits architectural coatings to no more than 50 g/L, which is classified as 'Low VOC.' Because VOC construction emissions are less than significant after mitigation, no further restrictions on VOC content are necessary.
Providing information on transit and ridesharing program and services to construction employees.	**Not Necessary:** Because construction criteria pollutant emissions are less than significant after mitigation, no further mitigation is necessary.
Providing meal options on-site or shuttles between the facility and nearby meal destinations for construction employees.	**Not Necessary:** Because construction criteria pollutant emissions are less than significant after mitigation, no further mitigation is necessary.
Requiring that all facility-owned and operated fleet equipment with a gross vehicle weight rating greater than 14,000 pounds accessing the site meet or exceed 2010 model year emissions equivalent engine standards as currently defined in California Code of Regulations Title 13, Division 3, Chapter 1, Article 4.5, Section 2025. Facility operators shall maintain records on-site demonstrating compliance with this requirement and shall make records available for inspection by the local jurisdiction, air district, and State upon request.	**Not Feasible:** Project end users are unknown at the time of Final EIR publication and, thus, it would be speculative to place restrictions on fleet equipment. Furthermore, imposing onerous requirements on the potential fleet of future unknown users could put the project at a competitive disadvantage by limiting the universe of potential future end users, and may be technologically infeasible due to the performance needs of the end user.
Requiring all heavy-duty vehicles entering or operated on the project site to be zero-emission beginning in 2030.	**Not Feasible:** Zero-emission heavy-duty vehicles are not widely available at the time of Final EIR publication. Imposing such a requirement for a technology in anticipation that it will become widely available is speculative. An absolute prohibition on the use of vehicles with internal combustion engineers could create hardships for future employees and visitors of the project site. The State of California is the appropriate level of government for creating incentives and/or mandates regarding the electrification of the State vehicle fleet.
Requiring all on-site equipment such as forklifts and yard trucks to electric with the necessary electrical charging stations provided.	**Not Feasible:** Project end users are unknown at the time of Final EIR publication and, thus, it would be speculative to place restrictions on on-site equipment. Furthermore, imposing onerous requirements on the potential equipment of future unknown users could put the project at a competitive disadvantage by limiting the universe of potential future end users, and may also be technologically infeasible due to the performance needs of the end user. Nonetheless, MM AIR-2c requires that electric landscaping equipment such as lawn mowers, leaf blowers, and chainsaws be used during operations.

Proposed Mitigation Measure	Analysis
	These technologies are widely available and because the proposed project would have landscaping, can be clearly shown to reduce emissions.
Requiring tenants to use zero-emission light- and medium-duty vehicles as part of business operations.	**Not Feasible:** Project end users are unknown at the time of Final EIR publication and, thus, no information is known about what types of light- and medium-duty vehicles would be used as part of business operations. Imposing onerous requirements on the potential vehicles of future unknown users could create hardships for future employees and visitors of the project site, could put the project at a competitive disadvantage by limiting the universe of potential future end users, and may also be technologically infeasible due to the performance needs of the end user.
Forbidding trucks from idling more than 2 minutes and requiring operators to turn off engines when not in use.	**Not Feasible:** State law limits idling to no more than 5 minutes. Limiting idling to fewer minutes would be very difficult to enforce and would create confusion between local and State vehicle idling limitations.
Posting both interior- and exterior-facing signs, including signs directed at all dock and delivery areas, identifying idling restrictions and contact information to report violations to the ARB, the air district, and the building manager.	**New Mitigation:** MM AIR-2e has been added to the Draft EIR requiring that anti-idling signage be posted in loading dock areas. This change is noted in Final EIR Section 5, Errata. The residual significance of Impact AIR-1 and AIR-2 remains significant and unavoidable.
Installing and maintaining, at the manufacturer's recommended maintenance intervals, an air monitoring station proximate to sensitive receptors and the facility for the life of the project, and making the resulting data public in real time. While air monitoring does not mitigate the air quality or greenhouse gas impacts of a facility, it nonetheless benefits the affected community by providing information that can be used to improve air quality or avoid exposure to unhealthy air.	**Not Effective:** This mitigation measure does not reduce emissions. As the commenter recognizes, air monitoring by itself does not mitigate the air quality or greenhouse gas impacts of a facility.
Constructing electric truck charging stations proportional to the number of dock doors at the project.	**Already Included as Mitigation:** MM GHG-1d requires electric vehicle charging stations in parking areas. It should be noted that electric trucks – particularly heavy-duty trucks – are not widely available at the time of Final EIR release. Therefore, installing additional charging stations at loading docks likely would not reduce emissions to any meaningful degree.
Constructing electric plugs for electric Transport Refrigeration Units at every dock door, if the warehouse use could include refrigeration.	**Already Included as Mitigation:** MM GHG-1d requires electrical outlets for TRUs at each loading dock.

Proposed Mitigation Measure	Analysis
Constructing electric light-duty vehicle charging stations proportional to the number of parking spaces at the project.	**Already Included as Mitigation:** MM GHG-1d requires electric vehicle charging stations in parking areas in accordance with CalGreen Tier 2 standards.
Installing solar photovoltaic systems on the project site of a specified electrical generation capacity, such as equal to the building's projected energy needs.	**Already Included as Mitigation:** MM GHG-1d requires the proposed project to be powered with 100 percent carbon-free electricity. This requirement could be met by installing on-site solar photovoltaic systems.
Requiring all stand-by emergency generators to be powered by a non-diesel fuel.	**Not Necessary:** Operational particulate matter emissions are less than significant and do not require mitigation. Sensitive receptor exposure to diesel particulate matter emissions is also less than significant and does not require mitigation. Thus, there is no basis under CEQA to impose mitigation stand-by emergency generators.
Requiring facility operators to train managers and employees on efficient scheduling and load management to eliminate unnecessary queueing and idling of trucks.	**Not Feasible:** As the future operators for the proposed project are as yet unknown, this measure would be difficult to enforce. Furthermore, emission reductions or other air quality benefits resulting from this measure are not able to be quantified due to the unknown specifics of the future operation. Therefore, this proposed measure would be ineffective in providing air quality or GHG benefits, as compared to the other measures being required for the proposed project which include requirements for timing of implementation and specific enforcement criteria.
Requiring operators to establish and promote a rideshare program that discourages single-occupancy trips and provides financial incentives for alternative modes of transportation including carpooling, public transit, and biking.	**New Mitigation:** MM AIR-2f has been added to the Draft EIR requiring that a TDM Program be implemented. This change is noted in Final EIR Section 5, Errata. The residual significance of Impact AIR-1 and AIR-2 remains significant and unavoidable.
Meeting CalGreen Tier 2 green building standards, including all provisions related to designated parking for clean air vehicles, electric vehicle charging, and bicycle parking.	**Already Included as Mitigation:** MM GHG-1c requires project buildings to meet CalGreen Tier 2 green building standards. MM GHG-1d requires electric vehicle charging stations in parking areas in accordance with CalGreen Tier 2 standards.
Achieving certification of compliance with LEED™ green building standards.	**Already Included as Mitigation:** MM GHG-1c requires project buildings to meet CalGreen Tier 2 green building standards, which are functionally equivalent to Leadership in Energy and Environmental Design (LEED™). Furthermore, the project architect is LEED™ accredited and has included various LEED™ design features into the proposed project.

Proposed Mitigation Measure	Analysis
Providing meal options on-site or shuttles between the facility and nearby meal destinations.	**Not Feasible:** Meals are a function of personal preference, dietary needs, economics, and the amount of time one has to eat. Given that the meal preferences of project workers are unknown and may change from day-to-day, requiring on-site meal options or a shuttle to off-site meal locations as a condition of project approval would be premature and might commit future end users to expensive programs with very limited effectiveness, if any, in reducing emissions. Future end users might freely decide to provide on-site opportunities for varieties of meal types.
Posting signs at every truck exit driveway providing directional information to the truck route.	**Not Necessary:** Both Devlin Road and Green Island Road are designated truck routes. Thus, whichever way trucks turn, they would be on a truck route that connects to SR-29. Hence, this mitigation measure would not reduce emissions.
Improving and maintaining vegetation and a tree canopy for residents in and around the project area.	**Not Feasible:** The project vicinity is entirely nonresidential. The nearest residential neighborhood is 4,000 feet to the south. Nonetheless, the proposed project would provide landscaping including trees along its street frontages and within parking areas.
Requiring that every tenant train its staff in charge of keeping vehicle records in diesel technologies and compliance with ARB regulations, by attending ARB approved courses. Also require facility operators to maintain records on-site demonstrating compliance and make records available for inspection to the local jurisdiction, air district, and State upon request.	**Not Feasible:** ARB regulations are enforced by the State and local agencies, and operators must comply with State rules and regulations to legally operate in California. This measure does not provide direct emission reductions or other air quality benefits; rather, it assumes that increased education may lead to reduced emissions. The measure would be onerous and difficult to enforce due to the unknown future operators of the proposed project and may put the project at a competitive disadvantage through the requirement of additional steps to educate staff on already existing requirements, while not providing effective or quantifiable air quality or GHG emission reduction benefits.
Requiring tenants to enroll in the United States Environmental Protection Agency (EPA) SmartWay program and requiring tenants to use carriers that are SmartWay carriers.	**Not Feasible:** The requirement that tenants enroll in the EPA SmartWay program would be onerous and difficult to enforce against unknown future end users of the project. Additionally, this measure would have limited emission reduction potential which is not possible to quantify. Requiring tenants to use carriers that are SmartWay carriers would put the project at a competitive disadvantage through limiting the potential universe of carrier providers for future operators, a limitation that would not be faced at similar logistics centers.

Proposed Mitigation Measure	Analysis
Providing tenants with information on incentive programs, such as the Carl Moyer Program and Voucher Initiative Program, to upgrade their fleets.	**New Mitigation:** MM AIR-2g has been added to the Draft EIR requiring that the project developer provide information on available ARB and BAAQMD incentive programs, such as the Carl Moyer Program and the Voucher Initiative Program, that support upgrading fleets. This change is noted in Final EIR Section 5, Errata. The residual significance of Impact AIR-1 and AIR-2 remains significant and unavoidable.

Response to SWAPE-3
The comment consisted of a disclaimer that SWAPE reserves the right to amend its findings if new information is made available. No response is necessary.

Response to SWAPE-4
The comment consisted of Matthew Hagemann's Curriculum Vitae. No response is necessary.

Response to SWAPE-5
The comment consisted of Paul Rosenfeld's Curriculum Vitae. No response is necessary.

RE: Giovannoni Logistics Center EIR

Monday, July 18, 2022

Dear Ms. Jones,

Sentinels of Freedom is a 501C3 Wounded and Injured Veterans Support Organization that owns a 25.44 acre vacant/undeveloped property adjacent to the Napa Logistic Park.

For the record, we'd like to offer to sell this property to American Canyon for a new Fire Station and Training Center to support Fire operations at the North Side of American Canyon adjacent and West of the new PG&E project. We believe this would be an

excellent site to support Fire Services for the Industrial growth in that sector.

I request that you please enter this communication and attachments into the EIR Public Comments on the upcoming Giovannoni Logistics Center EIR discussions and meetings.

We'll send the electronic records we have on our property and also my mail for your files.

1

We look forward to discussions with American Canyon on this concept and really think this could be a win/win for all concerned.

Thank you.

Very Respectfully, Mike Conklin

Mike Conklin

Chairman & CEO

Sentinels of Freedom (SENTINELS)

Response to SENTINELS-1
The Sentinels of Freedom, a 501(c3) nonprofit organization, indicated that it owns a 25.44-acre vacant property adjacent to Napa Logistics Park and would like to offer to sell the site to the City of American Canyon for the development of a fire station and training center.

The new "North" fire station is addressed in Master Response 2.

Response to SENTINELS-2
The comment consists of an Assessor's Parcel Map showing the location of the Sentinels' site. No response is necessary.

Response to SENTINELS-3
The comment consists of a conceptual site plan for warehouses on the Sentinels' site. No response is necessary.

Response to SENTINELS-4
The comment consists of a conceptual site plan for warehouses on the Sentinels' site. No response is necessary.

Re: **Comments on the Draft Environmental Impact Report – Giovannoni Logistics Center Project proposed by Buzz Oates Construction, Inc. (PL20-0042, PL20-0043 and SCH #2021010104)**

Dear Mr. Cooper and Ms. Jones:

We are writing on behalf of the Napa/Solano Residents for Responsible Development ("Napa/Solano Residents") to provide comments on the Draft Environmental Impact Report[1] prepared for the Giovannoni Logistics Center Project, PL20-0042, PL20-0043 and SCH #2021010104, ("Project") prepared by the City of American Canyon ("City") pursuant to the California Environmental Quality Act ("CEQA")[2]. 1

I. INTRODUCTION

The Project, proposed by Buzz Oates Construction, Inc. ("Applicant"), calls for development of up to 2.4 million square feet of cube warehouse space on a 208-acre project site located in the City of American Canyon ("City"), Napa County.[3] Phase 1 of the Project would be built on 94.7 acres on the eastern portion of the site and

[1] City of American Canyon, Draft Environmental Impact Report-Giovannoni Logistics Center Project (May 20, 2022) (hereinafter, "DEIR"), *available at* https://lf.cityofamericancanyon.org/WebLink/Browse.aspx?id=66927&dbid=1&repo=AmericanCanyon&cr=1
[2] Pub. Resources Code ("PRC") §§ 21000 *et seq.*
[3] DEIR, pg. 2-4.

printed on recycled paper

would include two high-cube warehouse buildings totaling 1,069,904 square feet.[4] One of the buildings would be rail-served by the adjacent Napa Branch Line and each building would provide docks, grade level roll-up doors and trailer parking stalls.[5] Phase 2 consists of approximately 1.3 million square feet of high-cube warehouse on the 113.1 acre western portion of the site.[6] No design-level site plans for Phase 2 have been prepared. The DEIR purports to analyze Phase 1 at a project level and Phase 2 at a program level.[7]

The Project site is currently undeveloped land; there are no structures on-site.[8] Vegetation consists primarily of non-native grasslands, with seasonal wetlands and associated plant species scattered throughout the site.[9] The headwaters of No-Name Creek are located in the northwestern corner of the property, and the Creek flows off the site at the northwestern corner of the property.[10] The drainage is hydrologically connected to the Fagan Slough, which flows into the Napa River.[11] The Applicant proposes to preserve approximately 44.8 acres of the Project site as an open-space wetlands preserve to conserve and manage vernal pool and other wetland and grassland resources.[12] The preserve is intended to mitigate wetlands and habitat impacts caused by the development of the Project.[13] The Project will also construct 110,766 square feet of storm drainage retention on-site, to include a network of underground piping to convey runoff to bioretention and detention basins in the northern portion of the site.[14] 1

The City owns an approximately 8 acre strip of land that bisects the site north to south, and an extension of Devlin Road is currently under construction on this parcel and is projected to be completed prior to Phase 1 of the Project.[15] Vehicular access to Phase 1 would be via four driveways on Green Island Road and four driveways on Devlin Road.[16] Two driveways on each road would be dedicated for truck access and the remaining two would be dedicated for passenger vehicle

printed on recycled paper

access.[17] Each of the Phase 1 buildings would include 430 parking stalls, including 10 ADA stalls, 26 electric vehicle parking stalls and nine Clean Air stalls.[18] Vehicular access to Phase 2 would also occur from both Green Island Road and Devlin Road.[19]

The DEIR fails to comply with CEQA's basic requirement to act as an "informational document." It lacks meaningful details in critical areas, such as air quality, health risk, biological resources, greenhouse gas ("GHG") and transportation impacts, without which the public and decisionmakers cannot adequately assess the Project's significant impacts. Because of the DEIR's shortcomings, it is deficient as a matter of law because it fails to properly disclose and mitigate the Project's potentially significant impacts. The DEIR also lacks substantial evidence to support the City's conclusions regarding the Project's impacts and proposed mitigation. These deficiencies render the document inadequate for purposes of compliance with CEQA. 1

We reviewed the DEIR, technical appendices, and reference documents with the assistance of our expert consultants, including air quality and hazardous materials expert James J.J. Clark, Ph.D., wetlands biologist Sarah Corbin, wildlife biologist Scott Cashen, and transportation expert Norman Marshall, whose comments and qualifications are included as Exhibit A, Exhibit B, Exhibit C, and Exhibit D, respectively.[20] The City must address and respond to their comments separately and fully.[21]

II. STATEMENT OF INTEREST

Napa/Solano Residents is an unincorporated association of individuals and labor organizations that may be adversely affected by the potential environmental impacts associated with Project development. Napa/Solano Residents includes American Canyon residents James Aken, Samantha Spangler, Evelyn Hernandez, and Alex Somodio, and members of the International Brotherhood of Electrical 2

Workers Local 180, Plumbers & Steamfitters Local 343, Sheet Metal Workers Local 104, Sprinkler Fitters Local 483, District Council of Ironworkers and their members and their families, and other individuals that live and/or work in the City of American Canyon and Napa/Solano Counties.

Napa/Solano Residents supports the development of sustainable commercial and industrial centers where properly analyzed and carefully planned to minimize impacts on public health and the environment. Logistics centers like the Project should avoid adverse impacts to air quality, biological resources, transportation, and public health, and should take all feasible steps to ensure unavoidable impacts are mitigated to the maximum extent feasible. Only by maintaining the highest standards can commercial and industrial development truly be sustainable.

The individual members of Napa/Solano Residents and the members of the affiliated labor organizations live, work, recreate and raise their families in and around American Canyon and Napa County. They would be directly affected by the Project's environmental and health and safety impacts. Individual members may also work constructing the Project itself. They would be the first in line to be exposed to any health and safety hazards which may be present on the Project site. They each have a personal interest in protecting the Project area from unnecessary, adverse environmental and public health impacts. 2

Napa/Solano Residents and its members also have an interest in enforcing environmental laws that encourage sustainable development and ensure a safe working environment for the members they represent. Environmentally detrimental projects can jeopardize future jobs by making it more difficult and more expensive for industry to expand in American Canyon and Napa County, and by making it less desirable for businesses to locate and people to live and recreate in the County, including the Project vicinity. Continued environmental degradation can, and has, caused construction moratoriums and other restrictions on growth that, in turn, reduces future employment opportunities.

Finally, Napa/Solano Residents is concerned with projects that can result in serious environmental harm without providing countervailing economic benefits. CEQA provides a balancing process whereby economic benefits are weighed against significant impacts to the environment.[22] It is in this spirit we offer these comments.

III. LEGAL BACKGROUND

CEQA requires public agencies to analyze the potential environmental impacts of their proposed actions in an EIR.[23] "The foremost principle under CEQA is that the Legislature intended the act to be interpreted in such manner as to afford the fullest possible protection to the environment within the reasonable scope of the statutory language."[24]

CEQA has two primary purposes. First, CEQA is designed to inform decisionmakers and the public about the potential significant environmental effects of a project.[25] "Its purpose is to inform the public and its responsible officials of the environmental consequences of their decisions before they are made. Thus, the EIR 'protects not only the environment but also informed self-government.'"[26] The EIR has been described as "an environmental 'alarm bell' whose purpose it is to alert the public and its responsible officials to environmental changes before they have reached ecological points of no return."[27] As the CEQA Guidelines explain, "[t]he EIR serves not only to protect the environment but also to demonstrate to the public that it is being protected."[28]

3

Second, CEQA requires public agencies to avoid or reduce environmental damage when "feasible" by requiring consideration of environmentally superior alternatives and adoption of all feasible mitigation measures.[29] The EIR serves to provide agencies and the public with information about the environmental impacts of a proposed project and to "identify ways that environmental damage can be avoided or significantly reduced."[30] If the project will have a significant effect on

printed on recycled paper

the environment, the agency may approve the project only if it finds that it has "eliminated or substantially lessened all significant effects on the environment" to the greatest extent feasible and that any unavoidable significant effects on the environment are "acceptable due to overriding concerns."[31]

While courts review an EIR using an "abuse of discretion" standard, "the reviewing court is not to 'uncritically rely on every study or analysis presented by a project proponent in support of its position. A clearly inadequate or unsupported study is entitled to no judicial deference."[32] As the courts have explained, a prejudicial abuse of discretion occurs "if the failure to include relevant information precludes informed decisionmaking and informed public participation, thereby thwarting the statutory goals of the EIR process."[33] "The ultimate inquiry, as case law and the CEQA guidelines make clear, is whether the EIR includes enough detail 'to enable who did not participate in its preparation to understand and to consider meaningfully the issues raised by the proposed project.'"[34] 3

IV. THE DEIR FAILS TO ADEQUATELY DESCRIBE THE PROJECT

The DEIR does not meet CEQA's requirements because it fails to include an accurate, complete and stable description of key Project components, rendering the DEIR's impact analysis inadequate. California courts have repeatedly held that "an accurate, stable and finite project description is the *sine qua non* of an informative and legally sufficient EIR."[35] CEQA requires that a project be described with 4

[31] PRC § 21081(a)(3), (b); CCR §§ 15090(a), 15091(a), 15092(b)(2)(A), (B); *Covington v. Great Basin Unified Air Pollution Control Dist.* (2019) 43 Cal.App.5th 867, 883.

printed on recycled paper

enough particularity that its impacts can be assessed.[36] Without a complete project description, the environmental analysis under CEQA is impermissibly limited, thus minimizing the project's impacts and undermining meaningful public review.[37]

4

Here, the DEIR's description of the Project is inconsistent and unstable, in that the size of the Project and buildout horizon change depending on the impact being analyzed. Moreover, the DEIR does not consistently analyze both phases of the Project.

A. The DEIR Does Not Consistently Apply The Buildout Horizon Or Building Sizes Set Forth In The Project Description.

The DEIR describes the Project as an approximately 2.4 million square foot logistics center on approximately 163 acres of the approximately 208-acre Project site.[38] The Project is to be developed in two phases: Phase 1 would include two high-cube warehouse buildings totaling approximately 1.1 million square feet on the 94.7 acre eastern portion of the site, and Phase 2 would develop 1.3 million square feet of warehouse on the 113.1 acre western portion of the site.[39] With respect Project buildout horizon, the DEIR states, "For purposes of providing a conservative, worst-case scenario, this Draft EIR assumes that Phases 1 and 2 would be *developed concurrently over a period of 18 months. As a practical matter, the proposed project would buildout over a period of years or decades.* Phase 1 would be developed first, followed by Phase 2 [emphasis added]."[40]

5a

As an initial matter, the DEIR's project description is flawed in that it assumes (and purports to analyze) a buildout scenario that admittedly will not occur, i.e. concurrent development of both phases over an 18-month period. If, "as a practical matter, the project would buildout over a period of years or decades," the DEIR's analysis should not be based on the unrealistic assumption that both phases will be developed concurrently in a year and a half. The DEIR's project description should set forth a buildout horizon that it reasonably expects to occur, so that the lead agency may properly assess the real-world expected impacts of the Project. The buildout horizon has important consequences for analyzing the Project's

[36] CCR § 15124; *see, Laurel Heights Improvement Assn. v. Regents of the Univ. of Cal.* (1988) 47 Cal.3d 376, 192–193.
[37] *Id.*
[38] DEIR, pg. 2-4.
[39] *Ibid.*
[40] *Id.,* pg. 2-9.

printed on recycled paper

significant impacts. For example, wetlands biologist Sarah Corbin notes that "a prolonged construction schedule that extends beyond 18 months and instead extends over several years (e.g., multiple nesting seasons and multiple "rainy seasons") increases the potential for construction-related impacts to aquatic resources."[41] 5a

Despite setting forth a specific assumption regarding buildout timeframe and purporting to use that assumption as the basis for its impacts analysis, the DEIR goes on to ignore its own "worst-case" assumption regarding Project buildout. Nowhere else in the DEIR is the Project described or analyzed as a concurrent (i.e., at the same time) buildout of both Phases over an 18-month period. For example, the DEIR's air quality analysis assumes that Phase 1 construction will begin in early 2022 and be complete 10 months later, with Phase 2 construction, with Phase 2 to begin immediately following and be completed 10 months later.[42] In other words, this analysis assumes a 20-month buildout of Phases 1 and 2 consecutively, rather than 18 months concurrently. Similarly, the DEIR's Health Risk Assessment models diesel particulate matter ("DPM") emissions assuming a 24-month buildout, i.e., 1 year of Phase 1 construction, immediately followed by 1 year of Phase 2 construction, followed by 30 years of operations for both Phases.[43] These inconsistencies matter because construction time frame is a key variable in the modeling used to estimate the Project's construction emissions for purposes of analyzing air quality and greenhouse gas impacts.[44] 5b

As with the Project's buildout horizon, the DEIR contains inconsistent descriptions of the size of the buildings to be constructed. The Project description describes Phase 1 as consisting of two buildings totaling 1,069,904 square feet.[45] However, immediately following that description, Table 2-1 summarizes Phase 1 as including Building A (627,976 square feet) and Building B (469,512 square feet), for a total of 1,097,488 square feet.[46] For purposes of modeling air emissions, Appendix B assumes that Building A will be 601,383 square feet and Building B will be 469,521 square feet, for a total of 1,070,904 square feet.[47] By modeling air emissions using smaller building sizes than those set forth in the Project 5c

[46] *Id.*, pg. 2-5.
[47] DEIR, Appendix B at pg. 1.

printed on recycled paper

description, the DEIR's emissions calculations reflect lower, and potentially inaccurate, construction and operational emissions.

These discrepancies must be addressed in a revised and recirculated EIR with accurate, stable and realistic descriptions of the size and buildout horizon of the Project so that decisionmakers can adequately assess the Project's significant impacts in all impact areas. 5c

B. The DEIR's Analysis Of Hydrological Impacts Fails To Consider Any Impacts Associated With Construction And Operation Of Phase 2 Of The Project.

Another example of the DEIR's analysis not matching the assumptions in the Project description (Phases 1 and 2 developed concurrently) is the analysis of hydrological impacts. This analysis focuses solely on Phase 1's impacts to runoff and downstream impacts, as if Phase 2 will never be constructed. While the DEIR purports to analyze stormwater and drainage impacts of both Phases, in reality only Phase 1 impacts are analyzed.

The currently undeveloped Project site includes No-Name Creek, which runs from east to west along the northern portion of the property and eventually drains into the Napa River. The Project's Phase 1 plans include a stormwater management system to collect and store runoff from the more than one million square feet of newly impervious surfaces (i.e., buildings and parking lots) that will be constructed as part of the Project. 6

The DEIR's analysis of hydrological impacts is based on the Preliminary Hydrological and Hydraulic Modeling study ("Hydrological Study"),[48] which purports to "model, assess, and outline how the changes in existing, and proposed land cover, along with the proposed construction of Devlin Road, will impact the hydrology and hydraulics of the creek directly downstream of the Project area and along the reach to its confluence with the Napa River."[49] Notably, the DEIR purports to use this Study to analyze hydrological impacts of both Phase 1 and Phase 2.[50] However, the Hydrological Study expressly only analyzed hydrological impacts of the development of Phase 1: "The first phase of the Project, referred to as the Giovannoni Logistics Center East and covered herein, proposes the construction

[48] DEIR, Appendix F.
[49] *Id.*, pgs. 1-2.
[50] *Id.,* pgs. 3.8-10, 3.8-12, 3.8-13.

printed on recycled paper

of two warehouses (gross square footage of the two buildings is roughly one million square feet) along with parking lots…on roughly 70 acres."[51]

The Hydrological Study divides the Project area into two drainage management areas ("DMAs") comprised of a mix of parking lot, roof area and pervious landscaping.[52] The two DMAs roughly correspond with the footprints of the two proposed Phase 1 buildings.[53] The modeling implicitly assumes no development of Phase 2 on the western portion of the Project site, although Phase 2 would add more than one million square feet of impervious surfaces. The hydrological impacts of Phase 1, i.e., whether the Project's storm management system can adequately control runoff and whether there will be downstream impacts, cannot be assessed without consideration of the additive effects of Phase 2 development. 6

V. THE DEIR FAILS TO ADEQUATELY DESCRIBE THE EXISTING BASELINE

The DEIR fails to accurately disclose the baseline environmental conditions related to the Project's biological impacts. As a result, the DEIR lacks the necessary baseline information against which to measure the Project's environmental impacts with regard to impacts to wetlands and wildlife habitat.

The existing environmental setting is the starting point from which the lead agency must measure whether a proposed project may cause a significant environmental impact.[54] CEQA defines the environmental setting as the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published, from both a local and regional perspective.[55] Describing the environmental setting accurately and completely for each environmental condition in the vicinity of the Project is critical to an accurate, meaningful evaluation of environmental impacts. The courts have clearly stated that, "[b]efore the impacts of a project can be assessed and mitigation measures considered, an [environmental review document] must describe the existing 7

[51] DEIR, Appendix F, pg. 1.

printed on recycled paper

environment. It is only against this baseline that any significant environmental effects can be determined."[56] 7

A. The DEIR Fails To Accurately Delineate Or Provide Any Functional Assessment Of The Existing Wetlands.

As discussed above, the Project site is currently undeveloped and contains several acres of both grassland and wetlands, which include palustrine emergent wetlands, seasonal wetlands, and vernal pools. Development of the Project will directly impact, i.e., fill and pave over, more than 4 acres of wetlands. The DEIR undertakes to analyze and mitigate these impacts, but fails at the most basic level: it fails to accurately delineate the full extent of the existing wetlands and provides no assessment at all of the wetlands' current functions. These errors and omissions make it impossible to adequately analyze the Project's wetlands impacts or whether the proposed mitigation will be effective. 8

1. The Project Site Wetlands Are Not Accurately Delineated.

Wetlands biologist Sarah Corbin reviewed the DEIR's wetlands impact analysis, including the supporting technical appendices, and found numerous errors and discrepancies that undermine the Project site's wetlands delineation report ("Delineation Report"), which provides the baseline against which the DEIR evaluates biological impacts.[57] For example, several of the wetland determination survey data sheets supporting the Delineation Report incorrectly failed to identify an observed plant species as a wetlands indicator species, meaning that the area surveyed was incorrectly classified as upland rather than wetland.[58] In addition, there is a glaring inconsistency with respect to a wetland area identified as Wetland IW-9 in the Delineation Report.[59] Wetland IW-9 is an isolated linear wetland in the southeast portion of the Project area that would partially coincide with or be immediately adjacent to the Project development footprint.[60] However, that wetland is absent from the October 2016 Confirmed Aquatic Resources Delineation Map, and this absence is carried through in the DEIR figures and analysis. Ms. Corbin finds that there "is no wetland determination data sheet to support the wetland's inclusion or exclusion and no discussion of the change in the DEIR or supporting 9

[60] *Ibid.*

printed on recycled paper

documents."[61] These errors mean that more wetland was present on the Project site during the delineation report fieldwork than is reflected in the resulting report and ultimately in the DEIR.[62]

The Delineation Report, and the required Army Corps of Engineers ("Corps") Jurisdictional Determination approving it, are nearly six years old. Corps Jurisdictional Determinations are valid for five years, meaning it will need to be updated before the Project can obtain the necessary Corps permits to fill any wetlands. Even though the Jurisdictional Determination was still valid in January 2021 when the Notice of Preparation for the DEIR was published, the wetlands delineation on which the DEIR's impact analysis is based is now out of date and does not accurately reflect current baseline conditions at the Project site. The Corps applies expiration dates to Jurisdictional Determinations because wetland boundaries are expected to change over time due to both natural (e.g., climate patterns) and human-caused activities.[63] Indeed, Ms. Corbin's review of recent aerial imagery of the Project site appear to demonstrate potential wetlands that were not identified as such in the delineation report.[64] For all of the foregoing reasons, the wetlands delineation must be updated to provide a proper baseline against which the Project's impacts can be accurately analyzed and the resulting analysis must be set forth in a revised and recirculated DEIR. 9

2. The DEIR Lacks Any Assessment of Wetland Functions

Wetlands can serve a number of important functions, such as providing rest and foraging habitat for migratory waterfowl, breeding habitat for amphibians and invertebrates, flood storage potential, and filtration of pollutants and excess nutrients surface water and groundwater.[65] The DEIR does not include a functional assessment of the Project site's existing wetlands and hence no functional impact analysis is provided (indeed, such analysis is not possible without the assessment). As Ms. Corbin explains, "[w]etlands impact analyses are incomplete without a functional assessment that evaluates hydrologic, water quality, and habitat functions of the site wetlands."[66] Without knowing the specific functions of the wetlands being impacted, it is therefore impossible to accurately assess those 10

[66] *Ibid.*

printed on recycled paper

impacts or to evaluate whether mitigation will adequately replace or mitigate those lost functions. While the DEIR states that a functional assessment will be completed with the Project's Wetland Mitigation and Monitoring Plan at some later date, that will be too late for the decisionmakers to evaluate this Project's wetlands impacts or to determine whether the proposed mitigation is appropriate.

To assess the environmental impacts of a proposed project, CEQA requires that the lead agency examine the changes to existing environmental conditions that would occur if the project were implemented.[67] Because the DEIR lacks any baseline description of the existing wetlands functions, analysis of the Project's impacts and proposed mitigation measures is impossible.[68] The DEIR must be revised and recirculated after including an appropriate functional assessment and proper analysis of the Project's wetlands impacts. 10

B. The DEIR Fails To Establish A Proper Baseline With Respect To Impacts To Biological Resources.

In addition to the DEIR's failure to provide a functional assessment of the Project site's wetlands, Mr. Cashen identifies additional deficiencies in the DEIR's description of the environmental setting.

First, the DEIR's conclusion that the Project would have no impact on the federally threatened vernal pool fairy shrimp is not supported by current scientific evidence. As Mr. Cashen explains, the Project site contains vernal pools and provides potential habitat for this species.[69] The DEIR relies on dry season vernal pool fairy shrimp surveys in summer of 2016 and wet season vernal pool fairy shrimp surveys in the winter of 2016-17.[70] Mr. Cashen states that the results of those surveys are outdated and can no longer be used to assume the absence of the species at the Project site.[71] The DEIR provides no evidence supporting its assumption that these several years old surveys accurately describe the Project site's environmental setting as of the time the Notice of Preparation of the DEIR was posted.[72] 11

[67] *See, e.g.,* 14 CCR § 15126.2(a).

[71] *Ibid.*
[72] *See,* 14 CCR § 15125.

printed on recycled paper

Vernal pool fairy shrimp disperse among individual pools through flooding, wind, birds, other vertebrates and various human activities.[73] This species can therefore rapidly colonize new pools or recolonize pools from which they have been extirpated.[74] Mr. Cashen cites several studies that recognize viable cysts can survive passage through the digestive tract of waterfowl, as well as attach to feathers of feet of wading birds, thus promoting long-distance dispersal of vernal pool fairy shrimp among pools. As thousands of vernal pool fairy shrimp were recently detected in a vernal pool near the Napa County Airport, approximately 2,700 feet from the Project site, and because waterfowl and shorebirds frequent the Napa County Airport site and the Project site, it reasonably foreseeable that birds have transported vernal pool fairy shrimp within the five years that have elapsed since the surveys supporting the DEIR were conducted. Negative results from five-year old surveys do not justify the DEIR's definitive determination that the Project will have no impact on vernal pool fairy shrimp.

The DEIR also relies on botanical field surveys conducted at the Project site in April-May 2021 and set forth in the Helm Biological Consulting report ("HBC report"). The DEIR states that based on these surveys, "no special-status plant species occur on the project site. Therefore, no impacts to special-status species would occur from construction of the proposed project. No mitigation is warranted for special-status plants."[75] Mr. Cashen explains why this conclusion is unsupported. 11

First, the surveys were conducted during a drought year. Many vernal pool plant species have seeds that can remain dormant for many years, an adaptation that allows them to survive drought periods.[76] The HBC report admits that nine of the rare plant species that could occur at the Project site are wetland-dependent and that below-average annual rainfall in 2020-21 could have affected the ability to detect the presence of such species.[77]

Second, the HBC Report surveys did not encompass the blooming periods of all of the target species. Specifically, Napa bluecurls is an annual herb that blooms between June and October. Mr. Cashen cites evidence documenting that, of 19 specimens of Napa bluecurls collected in Napa County, all 19 were collected

between July and September. Pappose tarplant is an annual herb that blooms between May and November. Although the HBC Report included surveys performed on May 4 and May 17, 2021, Mr. Cashen cites evidence showing that it is extremely rare for pappose tarplant to bloom that early in Napa County; the vast majority of such specimens have been collected in September and October.[78]

11

Because the HBC Report surveys were not conducted when all potentially occurring rare plants would be both evident and identifiable (as required by California Department of Fish and Wildlife survey protocols), there is insufficient evidence to support the DEIR's determination that "no special-status plan species occur on the project site."[79]

VI. THE DEIR FAILS TO DISCLOSE, ANALYZE AND MITIGATE POTENTIALLY SIGNIFICANT IMPACTS

An EIR must fully disclose all potentially significant impacts of a Project and implement all feasible mitigation to reduce those impacts to less than significant levels. The lead agency's significance determination with regard to each impact must be supported by accurate scientific and factual data.[80] An agency cannot conclude that an impact is less than significant unless it produces rigorous analysis and concrete substantial evidence justifying the finding.[81]

Moreover, the failure to provide information required by CEQA is a failure to proceed in the manner required by CEQA.[82] Challenges to an agency's failure to proceed in the manner required by CEQA, such as the failure to address a subject required to be covered in an EIR or to disclose information about a project's environmental effects or alternatives, are subject to a less deferential standard than challenges to an agency's factual conclusions.[83] In reviewing challenges to an agency's approval of an EIR based on a lack of substantial evidence, the court will 'determine de novo whether the agency has employed the correct procedures, scrupulously enforcing all legislatively mandated CEQA requirements.'[84]

Even when the substantial evidence standard is applicable to agency decisions to certify an EIR and approve a project, reviewing courts will not 'uncritically rely on every study or analysis presented by a project proponent in support of its position. A clearly inadequate or unsupported study is entitled to no judicial deference.'"[85] 12

A. The DEIR Fails To Disclose Or Adequately Analyze Transportation Impacts.

The DEIR concludes that the transportation impacts of the Project will be less than significant without mitigation. However, the transportation impacts analysis is flawed in numerous ways, most notably with respect to the Project's vehicle miles traveled ("VMT") impacts. In addition, the DEIR's faulty and unsupported conclusions with respect to VMT and trip generation completely undermine the DEIR's air quality and GHG analyses, which rely heavily on those same factors. 13

1. The DEIR's Significance Threshold For VMT is Not Based On Substantial Evidence.

The CEQA Guidelines authorize agencies to select "thresholds of significance" to assist in determining whether a project's effect will be deemed significant.[86] Lead agencies may rely on a previously adopted regulatory threshold, or may use thresholds on a case-by-case basis.[87] In either case, the selection of a threshold of significance must be supported by substantial evidence.[88] When an impact exceeds a CEQA significance threshold, the agency must disclose in the EIR that the impact is significant.[89] 14

The DEIR's VMT significance threshold is not supported by substantial evidence. The DEIR states that it relies on "established policies currently used by the OPR, Sacramento County, and the city of San Jose" in selecting its significance threshold: "a VMT impact would be identified at an industrial project if the project

printed on recycled paper

VMT per employee is higher than the regional average VMT per employee."[90] The DEIR defines "regional average VMT" as the nine county Bay Area average and asserts that this average is 23 miles per employee as reportedly stated by the City of Vallejo in its CEQA Transportation Impact Analysis Guidelines.[91] However, this is the entire extent of the "analysis" performed by the City in adopting 23 miles per employee as the VMT significance threshold in this DEIR. The DEIR doesn't make even the slightest effort to explain how Vallejo derived that number and whether it is an appropriate significance threshold for this Project. Nor is there any discussion as to why the nine county Bay Area—a region covering nearly 7000 square miles and including the full spectrum of land uses—provides a valid regional average against which to measure the impacts of this Project. 14

As discussed below, the City recently applied a lower, data-based VMT threshold to analyze the impacts of a comparable commercial distribution center project located less than 2 miles from the Project site, resulting in a finding of significant VMT impacts. By contrast, the significance threshold applied to the Project lacks any supporting data or discussion, and resulted in an unsupported finding of less than significant VMT impacts. This fails to comply with CEQA's requirements. The DEIR must be revised and recirculated to provide evidentiary support for the threshold selected for the Project, or the City must apply a more appropriate, data-based threshold to its VMT analysis.

2. The DEIR's VMT Estimates For The Project Are Inadequate As A Matter Of Law.

Determining whether a project may have significant effects plays a critical role in the CEQA process; this determination calls for careful judgment by the lead agency, based on scientific and factual data.[92] The CEQA Guidelines are explicit that, while the agency has discretion to choose the most appropriate methodology to evaluate a project's VMT impacts, any assumptions used to estimate VMT "should be documented and explained in the environmental document prepared for the project."[93] The Guidelines expressly apply section 15151's standard of adequacy to the VMT analysis: "the EIR should be prepared with a sufficient degree of analysis to provide decision makers with information which enables them to make a decision 15

[90] DEIR, pg. 3.2-17.
[91] *Ibid.*
[92] 14 CCR § 15064(b)(1).
[93] 14 CCR § 15064.3(b)(4).

printed on recycled paper

which intelligently takes account of environmental consequences."[94] The DEIR's VMT analysis complies with none of these CEQA requirements, as there is essentially no analysis and its conclusions rely on wholly unsupported and unexplained assumptions. A conclusory discussion of a significant environmental impact can support a court's determination that an EIR is inadequate as an informational document without reference to substantial evidence review.[95]

The DEIR includes no analysis of the Project's estimated VMT. Rather, it purports to pull a number from the California Statewide Travel Demand Model ("CSTDM") with no explanation of what the model is, how the number was computed or whether it is appropriately adopted as the estimated VMT for the Project. The entirety of the VMT "analysis" for this 2.4 million square foot warehouse Project is as follows:

> According to Statewide Travel Demand Model estimates, this project is located within a Traffic Analysis Zone (TAZ) with a projected VMT per employee of 16.24 miles. Because this per capita VMT rate is lower than the significance threshold of 23.0 miles, the project would be considered to have a less-than-significant impact.

15

The DEIR simply adopts the 16.24 number as the "Project VMT rate" with no further discussion.[96] No other information about the CSTDM is included in the DEIR; it is not even cited in the references for the Traffic Impact Study supporting the Transportation analysis.[97] The DEIR and supporting materials provide no information allowing the reader to verify the 16.24 number, and offer no explanation of what a TAZ is, what it purports to measure or why 16.24 miles per employee can simply be adopted as the estimated VMT for the Project. As transportation expert Norman Marshall states, "it is impossible to know how the DEIR arrived at 16.24 as the Project VMT using the CSTDM, because neither the DEIR nor the technical appendices contain any detail, analysis or calculations supporting that figure."[98]

The California Department of Transportation ("Caltrans"), which developed the CSTDM, includes the following language on the model's home webpage: "[t]he CSTDM provides an advanced tour/activity models to help Caltrans develop and evaluate transportation related policies and programs of projects that best meet our mobility goals. *This model is not an appropriate tool for individual project level analysis.*"[99] The DEIR does not discuss why, despite this admonition, it uses the CSTDM as the sole source for estimating this Project's VMT impacts. As Mr. Marshall points out, regional travel models are commonly used to estimate VMT, but the statewide model is too coarse to reliably estimate VMT for any particular project.[100]

In 2021, the City prepared an Initial Study/Mitigated Negative Declaration[101] ("IS/MND") for a 217,000 square foot wine distribution center located less than 2 miles from the Giovannoni Project site. In that IS/MND, the City assessed the potential VMT impacts as required by CEQA by performing data-based analyses, using multiple data sets, to estimate both the existing Napa County-wide average trip length/VMT per employee (which it adopted as the significance threshold) and the project area average trip length/VMT per employee. Notably, for that project the City used the same sets of data to derive both the significance threshold and the estimated project VMT. There, the City explained the nature of each of the data sets it utilized, the pros and cons of each, and the calculations used to derive a VMT significance threshold and project VMT. The City used CSTDM as one of several data points (while recognizing that TAZs' imprecise geography masks localized variation) in estimating county-wide and project area VMT per employee. It found that based on the CSTDM, the Countywide average VMT per employee was estimated to be 23.7, the Citywide average VMT per employee was 38.7 and the TAZ where the project is located has a VMT per employee rate of 38.1. After its full analysis using multiple data points, however, the City found a countywide average of 12.85 miles average commute length per employee, reduced that figure by 15% consistent with OPR guidance to establish a significance threshold of 10.92 miles, and found a project area average commute length per employee of 16.28 miles. Based on those findings, the project's VMT was a significant impact requiring mitigation.

printed on recycled paper

In stark contrast to the analysis performed for the wine distribution center IS/MND, the Giovannoni DEIR uses one data source to identify the significance threshold and another to estimate project VMT, and offers no explanation or analysis whatsoever of those numbers or whether the analyses from which they were derived are comparable. The DEIR is essentially asking the reader to compare one black box to another black box. It bears emphasizing that when the City actually performed a data-based VMT analysis of a similar project in a similar location, it came up with a significantly lower significance threshold (i.e., 10.92 miles per employee vs. 23 miles per employee.) But regardless of the actual numbers, it is clear that the Giovannoni DEIR doesn't come close to "including a sufficient degree of analysis to provide decision makers with information which enables them to make a decision which intelligently takes account" of the VMT impacts of the Project.[102] The DEIR's discussion of VMT is so cursory that it fails to comply with the basic CEQA requirement to discuss and analyze transportation impacts and makes the DEIR invalid as an informational document as a matter of law.[103] This lack of analysis is a fatal flaw which must be addressed in a revised and recirculated EIR. 15

3. The DEIR Underestimates Trip Length And Trip Generation, Which Leads To Underestimation Of GHG And Air Quality Impacts.

As explained above, the DEIR's conclusion that the Project will have no significant VMT impacts is not supported by substantial evidence, as the DEIR lacks any analysis or basis for that finding. As Mr. Marshall explains, the DEIR's chosen Project trip length (16.24 miles per employee) likely significantly underestimates average VMT per employee for the Project.[104] He explains why (consistent with Caltrans' admonition that the CSTDM is not appropriate for project level analysis) using large TAZs is not a reliable way of estimating average Project trip length.[105] He offers an alternative, more accurate method of estimating VMT per employee for this Project. He uses the U.S. Census Bureau's Longitudinal Employer-Household Dynamics ("LEHD") Origin-Destination Employment Statistics ("LODES") data that provide detailed geographic data about workers, jobs and commutes at the census block level.[106] Notably, the City also considered LODES data in the IS/MND discussed above. Census blocks are much smaller than 16

[102] *See* 14 CCR § 15151.

[106] *Id.,* pg. 8.

printed on recycled paper

the TAZs in the CSTDM; the City of American Canyon alone has 236 census blocks but only 2 TAZs. Therefore, the LODES data offer a more accurate look at actual commutes in the Project area than the DEIR's estimate purportedly derived from the CSTDM.

Using the LODES data, Mr. Marshall estimates average commute distances to American Canyon jobs by (1) calculating the direct ("as the crow flies") distance between the centers of each census block; (2) eliminating commutes of over 100 miles where the data may be spurious and inflate the average; and (3) multiplying by 110% to account for actual routing along roads.[107] The resulting average (mean) one way commute distance is 22 miles. To compare this average one-way commute distance to daily VMT per employee, the 22-mile average was further adjusted by (1) multiplying by 2 to account for round trips; (2) multiplying by 5/7 to account for a 5-day work week; and (3) multiplying by 95% to account for non-single occupant auto commutes.[108] The resulting daily mean VMT per employee is 29.9 which is significantly higher than the DEIR's estimate for the Project (16.24 VMT per employee) and exceeds the significance threshold adopted by the City for this Project (23.0 VMT per employee). Again, while CEQA gives lead agencies discretion to choose the most appropriate methodology to estimate a project's VMT, the assumptions underlying the analysis must be documented and explained in the EIR.[109] It also must contain a sufficient degree of analysis to enable decision makers to intelligently evaluate environmental impacts.[110] The DEIR contains virtually no analysis or explanation of its VMT estimates and therefore violates CEQA because it lacks enough detail "to enable those who did not participate in in its preparation to understand and to consider meaningfully the issues raised by the proposed project."[111]

16

Like the VMT analysis, the DEIR's trip generation analysis is not supported by substantial evidence, as it relies on unsupported assumptions which contradict assumptions made elsewhere in the DEIR.

First, the DEIR unreasonably and without justification assumes the lowest trip-generating uses for the Project. The DEIR estimates the number of vehicle

[107] *Id.*, pg. 9.
[108] *Ibid.*
[109] 14 CCR § 15064.3(b)(4).

printed on recycled paper

trips using daily trip rates published in the *Trip Generation Manual* (10th Edition) ("Manual").[112] However, as Mr. Marshall points out, the DEIR applies the lowest trip generation rate among several different types of high-cube warehouses.[113] The DEIR uses the Manual rates of 1.4 total vehicle trips and 0.22 truck trips per day attributable to "transload and short-term storage warehouses."[114] The DEIR contains no information to validate the selection of transload and short-term warehouses, as opposed to fulfillment center or parcel hub warehouses which have trip generation rates several times higher. Indeed, it appears that specific tenants and uses for the Project are unknown, a fact that is accounted for elsewhere in the DEIR: "as the proposed project is a speculative warehouse development which could accommodate cold storage and accompanying TRUs, this analysis [i.e., air emissions and GHG emissions modeling] considers two project scenarios: a cold warehouse project scenario and a dry warehouse project scenario."[115] The DEIR's Health Risk Assessment models cold storage uses only.[116] Despite recognizing the uncertainty as to the type of warehouse uses the Project will ultimately employ, and specifically analyzing for cold storage uses in other parts of the DEIR, the DEIR offers no justification for assuming that the Project will employ the lowest trip-generating use (and no cold storage use) in its transportation analysis. At a minimum, the transportation analysis should have assumed the Manual's trip generation rates for cold storage warehouses, which is 51% higher than the rate selected for total trips and more than 3 times higher than the rate for truck trips.[117] 16

Second, the DEIR uses the Manual's trip rates discussed above to project the Project's daily trips for passenger cars (2,832 daily trips) and trucks (528 daily trips) at full buildout of the Project. However, like the prospective warehouse functions used for the trip generation rate, the daily trips estimate is inconsistent with assumptions made elsewhere in the DEIR. The DEIR estimates that the Project will employ 3,643 workers at full buildout.[118] As Mr. Marshall points out, the employment estimate cannot be squared with the number of commute trips projected for the Project in the trip generation analysis.[119] Mr. Marshall assumes that the 3,643 workers make two trips per day (multiply by 2 for round trip commutes), work five days a week (multiply by 5/7) and that 95% of workers

[118] DEIR, pg. 2-8.
[119] Marshall Comments, pg. 5.

printed on recycled paper

commute alone (multiply by .95).[120] Using these assumptions, the Project would generate 4,944 daily commute trips, more than 2,000 trips over the number estimated by the DEIR using the unsupported trip rates in the trip generation analysis.

Finally, the DEIR claims that the truck trip rate assumed for the Project (.22 trips per 1,000 square feet) was estimated using the Manual rates and "validated using local vehicle classification counts conducted in June 2021."[121] As Mr. Marshall points out, though, the classification counts tell us only about the truck percentages in traffic in the vicinity of the proposed Project. "These percentages tell us nothing about truck trip generation for the proposed facility."[122]

Ultimately then, the trips lengths and trip generation rates used by the DEIR in its analysis of transportation impacts are unexplained, unsupported and/or contradicted by assumptions applied elsewhere in the DEIR. For all the reasons discussed above (and in the Marshall comments), the finding that the Project will not have significant transportation impacts—especially with respect to VMT—is not supported by substantial evidence. Moreover, these unsupported trip length and trip generation figures are key variables in the modeling used by the DEIR to analyze Project GHG and air quality impacts.[123] Given that the trip figures are unreasonably low, the modeling underestimates the Project's emissions of air pollutants and GHG. The City must therefore revise and recirculate the EIR with valid, supported trip length and trip generation estimates and using those new figures, re-analyze VMT, air quality and GHG impacts. 16

While the courts review an EIR using an "abuse of discretion" standard, "the reviewing court is not to 'uncritically rely on every study or analysis presented by a project proponent in support of its position. *A clearly inadequate or unsupported study is entitled to no judicial deference*."[124] As the courts have explained, "a prejudicial abuse of discretion occurs "if the failure to include relevant information precludes informed decisionmaking and informed public participation, thereby thwarting the statutory goals of the EIR process."[125] That is precisely the case here.

B. The DEIR Fails to Adequately Analyze Greenhouse Gas Impacts.

The DEIR's GHG analysis states that the Project would have significant impacts if it would (1) generate GHGs, either directly or indirectly, that may have a significant impact on the environment (GHG-1), (2) conflict with any applicable plan, policy or regulation adopted for the purpose of reducing the emissions of greenhouse gases (GHG-2), (3) result in potentially significant environmental impact due to wasteful, inefficient or unnecessary consumption of energy resources (GHG-3), or (4) conflict with or obstruct a state or local plan for renewable energy or energy efficiency.[126] Applying each of these significance criteria, the DEIR finds that the Project would not have significant impacts with respect to GHG emissions. As discussed below, these conclusions are not supported by substantial evidence. 17

1. Impact GHG-1

The DEIR analyzes whether the Project would generate GHGs that may have a significant impact on the environment by applying the CEQA Thresholds for Evaluating the Significance of Climate Impacts, recently adopted by the Bay Area Air Quality Management District ("BAAQMD").[127] These thresholds set forth specific criteria for determining whether new land use development projects contribute their "fair share"[128] of what is required to meet California's goal of carbon-neutrality by 2045. BAAQMD's thresholds require that new projects must incorporate either A or B from the following: 18

A. Projects must include, at a minimum, the following project design elements:

1. Buildings

a. The project will not include natural gas appliances or natural gas plumbing (in both residential and nonresidential development).
b. The project will not result in any wasteful, inefficient, or unnecessary energy usage as determined by the analysis required under CEQA Section 21100(b)(3) and Section 15126.2(b) of the State CEQA Guidelines.

[128] *See, Center for Biological Diversity v. Department of Fish & Wildlife* (2015) 62 Cal. 4th 204, 220-23.

printed on recycled paper

2. Transportation

a. Achieve a reduction in project-generated vehicle miles traveled (VMT) below the regional average consistent with the current version of the California Climate Change Scoping Plan (currently 15 percent) or meet a locally adopted Senate Bill 743 VMT target, reflecting the recommendations provided in the Governor's Office of Planning and Research's Technical Advisory on Evaluating Transportation Impacts in CEQA:

i. Residential projects: 15 percent below the existing VMT per capita
ii. Office projects: 15 percent below the existing VMT per employee
iii. Retail projects: no net increase in existing VMT
b. Achieve compliance with off-street electric vehicle requirements in the most recently adopted version of CALGreen Tier 2.

B. Projects must be consistent with a local GHG reduction strategy that meets the criteria under State CEQA Guidelines Section 15183.5(b).[129]

18

In analyzing the Project's operational GHG impacts (GHG-1), the DEIR adopts these thresholds of significance, "with minor refinements."[130] The refinements recognize that, with respect to VMT, the BAAQMD Thresholds refer to residential, office or retail projects, but not industrial projects like this one. The DEIR adopts the BAAQMD approach used for office projects, i.e., whether the Project achieves a 15 percent reduction below the existing VMT per employee.[131] In analyzing whether the Project satisfies this criterion, the DEIR relies solely on the VMT analysis contained in the Traffic Impact Study ("TIS") prepared for the Project.[132] The DEIR asserts a "29 percent reduction in employee VMT when compared to the existing regional VMT. As discussed [in the TIS], the region's existing average daily employee VMT is 23 miles while the proposed project's employee VMT would be 16.24 miles."[133]

As discussed in detail above, however, neither the DEIR's VMT discussion nor the TIS on which it is based contain any analysis or information supporting the conclusion that the relevant regional average VMT is 23 miles per employee or that

[129] BAAQMD Thresholds, pg. 2.

[132] *Id.*, pg. 3.6-56.
[133] *Ibid.*

printed on recycled paper

the Project VMT will be 16.24 miles per employee. Indeed, those conclusions are contradicted by the City's own analysis of a similar project and by the analysis performed by transportation expert Norman Marshall. Because the DEIR's claimed 29 percent reduction in VMT is totally unsupported, the conclusion that the Project complies with the modified BAAQMD significance thresholds adopted by the City is not supported by substantial evidence. 18

2. Impact GHG-2

The DEIR purports to analyze the Project's consistency with "the applicable plan adopted for the purpose of reducing GHG emissions."[134] Citing BAAQMD's CEQA Air Quality Guidelines, the DEIR states that for this impact to be less than significant, the Project must demonstrate consistency with the applicable GHG emissions reduction plan.[135] Like the BAAQMD Thresholds for evaluating climate impacts (set forth above), the BAAQMD CEQA Air Quality Guidelines define a qualified GHG reduction strategy by reference to State CEQA Guidelines section 15183.5.[136] Section 15183.5(b) sets forth specific elements for qualified GHG emissions reductions plans that may be used in later project level analysis of cumulative GHG impacts.[137] "An environmental document that relies on a greenhouse gas reduction plan for a cumulative impacts analysis must identify those requirements specified in the plan that apply to the project, and, if those requirements are not otherwise binding and enforceable, incorporate those requirements as mitigation measures…"[138] 19a

The DEIR purports to assess the Project's GHG impacts with respect to three "applicable plans adopted to reduce GHG emissions," i.e., the California Air Resources Board ("CARB") 2017 Scoping Plan, the Metropolitan Transportation Commission ("MTC") Plan Bay Area 2050, and the City of American Canyon's Energy Efficient Climate Action Plan ("EECAP"). [139] The DEIR makes no showing that any of these is a qualified GHG emissions reduction plan pursuant to CEQA Guidelines section 15183.5(b). Indeed, the DEIR expressly recognizes that American Canyon's EECAP "does not meet the requirements to be considered a qualified GHG reduction strategy capable of being tiered from under CEQA

[134] *Id.*, pg., 3.6-46.

[139] DEIR, pg. 3.6-61.

printed on recycled paper

Guidelines section 15183.5(b)."[140] Nor does the DEIR contain any discussion of the elements of a qualified GHG emissions reduction plan set forth in section 15183.5(b) with respect to the 2017 Scoping Plan or MTC Plan Bay Area 2040. The DEIR fails to explain why consistency with these plans is an appropriate significance threshold for GHG impacts, and the subsequent conclusion that the Project will have no significant impacts is not supported by substantial evidence. 19a

Even if the cited plans were qualified GHG emissions reduction plans, the DEIR's analysis is riddled with holes and cannot support a finding of no significant impact. With respect to the MTC Plan Bay Area, the DEIR's analysis simply makes no sense:

> As part of the implementing framework for Plan Bay Area 2050, local governments have identified planned development areas to focus growth. The project site is within the Napa County Airport Land Use Compatibility Plan area. Thus, the proposed project would be consistent with the overall goals of Plan Bay Area, which include concentrating new investment in areas that would encourage job growth. In addition, the proposed project would be developed in an area with existing infrastructure. Therefore, the proposed project would generally not conflict with the land use concept plan in Plan Bay Area 2050.[141] 19b

What is missing from this series of seemingly unrelated sentences is any mention of GHG or any specific requirements in the plan to reduce GHG emissions. Vague assertions that the Project is "consistent with overall goals" and "generally would not conflict with land use concepts" clearly do not support a finding of consistency with an applicable plan adopted for the purpose of reducing GHG emissions.

The DEIR's analysis of the Project's consistency with the 2017 Scoping Plan is similarly specious. The DEIR identifies a series of nine specific emissions reduction measures from the Scoping Plan and purports to analyze the Project's consistency with those measures.[142] However, immediately before listing these measures, the DEIR states "[a]s shown in Table 3.6-6, *none of the measures are* 19c

[140] *Id.*, pg. 3.6-54; see also pg. 3.6-38.
[141] DEIR, pg. 3.6-64.
[142] *Id.,* Table 3.6-6 at pgs. 3.6-66—3.6-68.

printed on recycled paper

applicable to the proposed project [emphasis added]."[143] Following Table 3.6-6, the DEIR continues, "[a]s shown in Table 3.6-6, the proposed project's implementation would not conflict with the reduction measures proposed in SB 32. As such, the proposed project would not conflict with any applicable plan, policy, or regulation adopted to reduce GHG emissions."[144] The reader is left to guess how the lack of conflict with a series of inapplicable measures demonstrates consistency with an applicable plan adopted for the purpose of reducing GHG emissions. 19c

Finally, the DEIR analyzes the Project's consistency with American Canyon's EECAP which, again, is admittedly not a qualified GHG emissions reduction plan. Seven different GHG emissions reduction measures are identified, five of which are found to be inapplicable to the Project.[145] The two measures applicable to the Project are (1) new construction should have solar ready roofs that are pre-wired and ready for the installation of solar photovoltaic panels and solar water heating systems and (2) the project should reduce water use through building and landscape design and improvements. [146] The DEIR claims that the Project would include roof structures designed to accommodate additional weight for rooftop solar (not that it will be pre-wired and ready for installation) and would include water efficient landscaping and include water use reduction methods. The DEIR does not say that these measures will be binding and enforceable on the Project Applicant, nor are they included as mitigation measures. Unenforceable statements that the Project will comply with these two measures contained in a non-qualified GHG emissions reduction plan cannot and does not support a finding that the Project is consistent with a qualified GHG emissions reduction plan.[147] 19d

3. Impact GHG-3

The DEIR asserts that a significant impact would occur if the Project would result in the inefficient, wasteful or unnecessary use of energy, i.e., if the Project would conflict with any of the following energy conservation goals: (1) decreasing overall per capita energy consumption, (2) decreasing reliance on fossil fuels, and (3) increasing reliance on renewable energy sources.[148] With respect to the first goal, the DEIR again cites the unsupported assumption that the Project will result in an 20

printed on recycled paper

approximately 29 percent reduction in employee VMT from regional average estimates, and asserts that therefore overall energy consumption related to employee transportation would decrease from that experienced by the region's current average employee transportation behavior. Once again, the DEIR builds on its unsubstantiated VMT analysis, which undermines the conclusion that the Project will decrease overall energy consumption related to employee vehicle use. The DEIR's finding of no significant impact with respect to Impact GHG-3 is therefore not supported by substantial evidence. 20

Because the DEIR's GHG analysis fails to employ appropriate significance thresholds and lacks substantial evidence supporting the finding of no significant GHG impacts, the DEIR must be revised and recirculated with an appropriate GHG analysis.

C. The DEIR Fails to Disclose, Analyze or Mitigate the Project's Potentially Significant Air Quality Impacts.

The DEIR's air quality analysis concludes, with respect to health risks to sensitive receptors, that neither the Project's construction or operation will cause a significant impact.[149] This conclusion is not supported by substantial evidence because the health risk assessment ("HRA") on which it is based fails to consider (1) impacts from exposure to all toxic air compounds ("TAC") in diesel exhaust, and (2) the effects on emissions from building downwash. In addition, the DEIR fails to consider and incorporate a number of feasible mitigation measures to reduce emissions of air pollutants and GHGs. 21

1. The Health Risk Assessment Fails To Consider Impacts Of TAC Emissions.

The DEIR fails to analyze the potentially significant air quality impacts from the gaseous form of diesel exhaust. As Dr. Clark explains, diesel exhaust is composed of particulate matter as well as vapor.[150] The DEIR does not account for the vapor components of diesel emissions in its HRA, and thus fails as an informational document as it does not provide an analysis of the full range of the Project's potential health impacts. 22

[149] DEIR, pg. 3.2-63.
[150] Clark Comments, p. 4.

printed on recycled paper

A lead agency's significance determination must be supported by accurate scientific and factual data.[151] An agency cannot conclude that an impact is less than significant unless it produces rigorous analysis and concrete substantial evidence justifying the finding.[152] These standards apply to the DEIR's analysis of the air quality impacts of the Project.

In *Sierra Club v. County of Fresno*, the California Supreme Court affirmed CEQA's mandate to protect public health and safety by holding that an EIR fails as an informational document when it fails to disclose the public health impacts from air pollutants that would be generated by a development project.[153] In *Sierra Club*, the Supreme Court held that the EIR for the Friant Ranch Project—a 942-acre master-planned, mixed-use development with 2,500 senior residential units, 250,000 square feet of commercial space, and open space on former agricultural land in north central Fresno County—was deficient as a matter of law in its informational discussion of air quality impacts as they connect to adverse human health effects.[154] As the Court explained, "a sufficient discussion of significant impacts requires not merely a determination of whether an impact is significant, but some effort to explain the nature and magnitude of the impact."[155] The Court concluded that the County's EIR was inadequate for failing to disclose the nature and extent of public health impacts caused by the project's air pollution. The EIR failed to comply with CEQA because the public, after reading the EIR, "would have no idea of the health consequences that result when more pollutants are added to a nonattainment basin."[156] CEQA mandates discussion, supported by substantial evidence, of the nature and magnitude of impacts of air pollution on public health.[157]

[155] *Id.* at 519, citing *Cleveland National Forest Foundation v. San Diego Assn. of Governments* (2017) 3 Cal.5th 497, 514–515.
[156] *Id.* at 518. CEQA's statutory scheme and legislative intent also include an express mandate that agencies analyze human health impacts and determine whether the "***environmental effects of a project will cause substantial adverse effects on human beings, either directly or indirectly***." (Public Resources Code § 21083(b)(3) (emphasis added).) Moreover, CEQA directs agencies to "take immediate steps to identify any critical thresholds for the ***health and safety of the people*** of the state and take all coordinated actions necessary to prevent such thresholds being reached." (Public Resources Code § 21000(d) (emphasis added).)

printed on recycled paper

In *Berkeley Jets*, the Court of Appeal held that an EIR must analyze the impacts from human exposure to toxic substances.[158] In that case, the Port of Oakland approved a development plan for the Oakland International Airport.[159] The EIR admitted that the Project would result in an increase in the release of TACs and adopted mitigation measures to reduce TAC emissions, but failed to quantify the severity of the Project's impacts on human health.[160] The Court held that mitigation alone was insufficient, and that the Port had a duty to analyze the health risks associated with exposure to TACs.[161] As the CEQA Guidelines explain, "[t]he EIR serves not only to protect the environment but also to demonstrate to the public that it is being protected."[162]

The failure to provide information required by CEQA makes meaningful assessment of potentially significant impacts impossible and is presumed to be prejudicial.[163] Challenges to an agency's failure to proceed in the manner required by CEQA, such as the failure to address a subject required to be covered in an EIR or to disclose information about a project's environmental effects or alternatives, are subject to a less deferential standard than challenges to an agency's factual conclusions.[164] Courts reviewing challenges to an agency's approval of an EIR based on a lack of substantial evidence will "determine de novo whether the agency has employed the correct procedures, scrupulously enforcing all legislatively mandated CEQA requirements."[165]

22

CARB defines diesel exhaust as a complex mixture of inorganic and organic compounds that exists in gaseous, liquid, and solid phases.[166] CARB and the United States Environmental Protection Agency ("U.S. EPA") identify 40 components of diesel exhaust as suspected human carcinogens, including formaldehyde, 1,3-butadiene, and benzo[a]pyrene.[167] The gas and particle components both contribute to health risks. The inhalation unit risk factor identified by OEHHA for use in risk assessments is for the DPM fraction of diesel exhaust and not the vapor phase

printed on recycled paper

components identified by CARB and U.S. EPA.[168] Here, the City only used the DPM fraction of diesel exhaust in its analysis of the construction and operational emissions and ignores the presence of TACs being emitted with diesel exhaust.[169] By failing to include an analysis of the additional TAC components of diesel exhaust, the DEIR does not provide a full picture of the Project's potential health impacts and fails as an informational document as required by CEQA. The County must update the HRA with the TAC impacts included and include the results in a revised and recirculated EIR. 22

2. The Modeling Used For The Health Risk Assessment Failed To Account For Building Downwash.

Dr. Clark reviewed the AERMOD modeling used by the DEIR to support the HRA and found that the modeling has a significant flaw: it fails to account for the impact on air emissions from building downwash.[170] Building downwash occurs as wind flows over and around buildings and impacts the dispersion of pollution from nearby sources.[171] A plume of contaminants caught in the path of this flow is drawn into the wake, temporarily trapping it in a recirculating cavity.[172] This downwash effect leads to higher ground-level concentration of chemicals emitted from sources and increases as the relative difference between the release height and top of the building increases.[173] For the closest receptors to the Project site, the residences to the east of the Project, this difference will create an additional air quality impact that is not accounted for in the City's analysis.[174] Omission of the building downwash effect underestimates the exposure point concentrations for receptors near the building(s). The City should update its HRA to account for this effect and include the results in a revised and recirculated EIR. 23

3. **The DEIR Fails to Consider and Implement All Feasible Mitigation Measures to Reduce Project Emissions.**

In response to the Notice of Preparation of the DEIR for this Project, CARB provided a letter to the City stating that "the final design of the Project should include all existing and emerging zero-emission technologies to minimize diesel PM 24

and oxides of nitrogen (NO_x) emissions, as well as the greenhouse gases that contribute to climate change."[175] CARB also encouraged the City and the Applicant to implement the measures listed in Attachment A to its letter, in order to reduce the Project's construction and operational air pollution emissions.[176] Dr. Clark echoes CARB's suggestion, and provides his own list of mitigation measures that include CARB's proposals and others proposed by Air Quality Management Districts in California:

1. Include contractual language in tenant lease agreements that requires tenants to use the cleanest technologies available, and to provide the necessary infrastructure to support zero-emission vehicles and equipment that will be operating on site.
2. Include contractual language in tenant lease agreements that requires all TRUs entering the project site be plug-in capable.
3. Include contractual language in tenant lease agreements that requires future tenants to exclusively use zero-emission light and medium-duty delivery trucks and vans.
4. Include contractual language in tenant lease agreements requiring all TRUs, trucks, and cars entering the Project site be zero-emission.
5. Include contractual language in tenant lease agreements that requires all heavy-duty trucks entering or on the project site to be model year 2019 or later, expedite a transition to zero-emission vehicles, and be fully zero-emission beginning in 2030.
6. Include contractual language in tenant lease agreements that requires the tenant be in, and monitor compliance with, all current air quality regulations for on-road trucks including CARB's Heavy-Duty (Tractor-Trailer) Greenhouse Gas Regulation,[177] Periodic Smoke Inspection Program (PSIP),[178] and the Statewide Truck and Bus Regulation.[179]

24

[175] DEIR, Appendix A, February 8, 2021 letter from Heather Arias to Brent Cooper.
[176] *Ibid.*, Attachment A.
[177] In December 2008, CARB adopted a regulation to reduce greenhouse gas emissions by improving the fuel efficiency of heavy-duty tractors that pull 53-foot or longer box-type trailers. The regulation applies primarily to owners of 53-foot or longer box-type trailers, including both dry-van and refrigerated-van trailers, and owners of the heavy-duty tractors that pull them on California highways. CARB's Heavy-Duty (Tractor-Trailer) Greenhouse Gas Regulation is available at: https://www.arb.ca.gov/cc/hdghg/hdghg.htm.
[178] The PSIP program requires that diesel and bus fleet owners conduct annual smoke opacity inspections of their vehicles and repair those with excessive smoke emissions to ensure compliance. CARB's PSIP program is available at: https://www.arb.ca.gov/enf/hdvip/hdvip.htm.
[179] The regulation requires that newer heavier trucks and buses must meet particulate matter filter requirements beginning January 1, 2012. Lighter and older heavier trucks must be replaced starting

printed on recycled paper

7. Include contractual language in tenant lease agreements restricting trucks and support equipment from idling longer than five minutes while on site.
8. Include rooftop solar panels for each proposed warehouse to the extent feasible, with a capacity that matches the maximum allowed for distributed solar connections to the grid.
9. Have truck routes clearly marked with trailblazer signs, so that trucks will not enter residential areas.
10. Limit the daily number of trucks allowed at the Proposed Project to levels analyzed in the CEQA document. If higher daily truck volumes are anticipated to visit the site, the Port as the Lead Agency should commit to re-evaluating the Proposed Project through CEQA prior to allowing this land use or higher activity level. 24
11. Ensure that any check-in point for trucks is well inside the Proposed Project site to ensure that there are no trucks queuing outside of the facility.
12. Establish overnight parking within the industrial building where trucks can rest overnight.
13. Establish area(s) within the Proposed Project site for repair needs.[180]

The DEIR fails to consider or implement these feasible mitigation measures.

D. The DEIR Fails to Disclose, Analyze or Mitigate Hydrological Impacts

Wetland biologist Sarah Corbin identifies several potentially significant hydrological impacts that are not disclosed and/or are inadequately analyzed. She also cites several ways in which the DEIR fails to demonstrate the efficacy of the proposed wetlands mitigation set forth in MM BIO-3a-3d. 25

1. The DEIR Fails To Disclose Or Adequately Analyze Hydrologic Impacts.

First, as discussed above, the lack of an accurate wetlands delineation and the failure to perform any functional assessment means that the DEIR cannot and does not describe or analyze the nature and extent of wetlands impacts. This 26

January 1, 2015. By January 1, 2023, nearly all trucks and buses will need to have 201 0 model year engines or equivalent. CARB's Statewide Truck and Bus Regulation is available at: https://www.arb.ca.gov/msprog/onrdiesel/onrdiesel.htm

[180] Clark Comments, pgs. 7-8.

printed on recycled paper

failure alone requires that the DEIR be revised and recirculated with a full disclosure and analysis of potentially significant wetlands impacts.

Second, the DEIR states that underground piping will convey stormwater from the Project's new pollution-generating impervious surfaces to bioretention and detention basins on the north boundary of the Project.[181] The DEIR further identifies "passive or active control devise [sic] to allow treated stormwater to enter the wetland swale," i.e. the created wetlands in the wetland preserve area.[182] However, the DEIR fails to discuss how drainage patterns to and hydrology sources in the unimpacted and created wetlands will be maintained. Without pre- and post-Project water budget analyses for the site wetlands, impacts to the "preserved" wetlands area cannot be properly evaluated and the DEIR's determination that additional wetlands will not be impacted is not supported by substantial evidence.[183]

Third, the Project proposes use of a specialized biosoil in the bioretention facility to remove pollutants from stormwater runoff. However, the DEIR also states that "the wetland preserve would facilitate the natural sequestration of pollutants of stormwater leaving the project site."[184] Using the wetland preserve as part of the Project's post-construction stormwater management strategy (i.e., to filter pollutants) will have long term detrimental impacts to these wetlands.[185] CEQA requires that if a mitigation measure itself would create significant impacts, those impacts must be discussed in the EIR.[186] These impacts are neither described nor analyzed in the DEIR, in violation of CEQA. 26

Fourth, the DEIR fails to disclose or analyze potentially significant indirect impacts to the Project site wetlands. As Ms. Corbin explains, buffers around wetland areas are critical to ensuring the long-term viability of those sites and may provide habitat or corridors necessary for the ecological functioning of the wetlands.[187] The importance of such buffers are emphasized in the Army Corps of Engineers mitigation guidelines for vernal pools, which require at least 100 feet

[181] Corbin Comments, pg. 4; DEIR, pg. 3.8-13.
[182] DEIR, Exh. 3.3-4.

[187] Corbin Comments, pg. 5.

printed on recycled paper

buffers "around all vernal pools and mitigation sites."[188] Such buffers should consist of "native vegetation or regionally characteristic annual grassland without cut or fill as a result of adjacent development" and the "appropriate buffer width will depend on adjacent land uses."[189]

Here, buffer widths between wetlands and the Project footprint are not provided but the DEIR's figure scales suggest they are less than 100 feet in many places, particularly adjacent to the Project footprint's northern boundary.[190] In addition, buffers surrounding several wetland areas are identified in the DEIR as proposed landscape areas, which suggests they will not consist of "native vegetation or regionally characteristic annual grassland without cut or fill as a result of adjacent development," per Corps guidelines. Indirect impacts to these wetland areas from disturbed or landscaped buffers are not disclosed or analyzed in the DEIR. 26

Finally, the connections and corridor between the wetlands in the southeastern Project area (Wetlands IW-7 to IW-10) and the remaining wetland complex to the north and east will disappear once the Project is developed.[191] This corridor disconnection, the overall reduction of undeveloped/unlandscaped buffer widths that will remain post-Project development and the indirect effects on the remaining site wetlands are not disclosed or analyzed in the DEIR. These potentially significant, unmitigated impacts must be fully analyzed in a revised and recirculated EIR.

2. The DEIR Contains No Evidence That Proposed Mitigation Will Be Effective.

In addition to the failure to describe and analyze potentially significant impacts to wetlands, the DEIR fails to demonstrate that the proposed mitigation measures will be effective in reducing the Project's significant wetlands impacts. Courts do not defer to determinations that mitigation measures will work when their efficacy is not apparent and there is no evidence in the record showing that they will be effective in remedying the identified impact.[192] 27

[188] *Id.,* citing U.S. Army Corps of Engineers (Corps), 2016b, Draft mitigation and monitoring guidelines for vernal pools: U.S. Army Corps of Engineers South Pacific Division, November, 23 p.6, available: https://www.spd.usace.army.mil//Portals/13/docs/regulatory/publicnotices/DVPGL.pdf.

printed on recycled paper

The DEIR includes mitigation measures MM BIO-3a—BIO-3d, which would create a "wetland preserve" area adjacent to the northern boundary of the Project site.[193] This plan proposes to preserve 7.58 acres of existing seasonal wetlands and 0.13 acre of vernal pool, create 0.992 acre of seasonal wetlands in advance of or concurrent with Phase 1 development, and create 2.57 acres of seasonal wetlands and 1.13 acres of vernal pools in advance of Phase 2.[194] The DEIR concludes that implementation of these measures would offset impacts to the Project site wetlands "in-kind" and ensure that there is no net loss of wetland area, "thus reducing potential impacts to a level considered less than significant."[195]

As Ms. Corbin and Mr. Cashen explain, while the wetlands mitigation measures may result in no net loss of *wetland area*, there is no discussion, let alone evidence, to support the conclusion that the mitigation will replace lost wetland *functions and value*.[196] As discussed, neither the DEIR nor the supporting documentation contain any assessment of the wetland functions that will be lost by the development of the Project. Because of this failure, Ms. Corbin finds "we are unable to evaluate if the proposed mitigation will adequately replace lost wetland function."[197]

27

Mr. Cashen echoes this criticism of the DEIR, noting that despite recognizing the impacts to several acres of wetland, "nowhere does the DEIR discuss the ecological functions of the wetlands at the Project site."[198] The wetlands and surrounding grasslands on the site currently occupy more than 200 acres of undeveloped land, which provide habitat for a variety of plant and bird species. After development, the "wetland preserve" would be limited to a 44.8 acre area that would "(a) be located between the Project site and the Napa Logistics Center site [an adjacent large warehouse development]; (b) be bisected by the Devlin Road Vine Trail Extension Project, and (c) have no connectivity to any other open space lands. Thus, the preserve would function as a habitat "island" surrounded by urban (industrial) development."[199] The preserve would be subject to ongoing disturbance caused by traffic, noise and human activity associated with Project operation, which would degrade the preserve's functions as wildlife habitat.[200]

printed on recycled paper

Given the foregoing, the failure to assess the existing wetlands functions or to analyze whether the wetland preserve will mitigate those functional losses is a glaring omission. "Although the proposed mitigation might ensure no net loss of *wetland area,* it would not ensure no net loss of wetland function and values." [201] Without an understanding of existing wetland function, it is not possible to determine whether the proposed mitigation will in fact replace or mitigate those lost functions. The DEIR therefore lacks any evidence demonstrating that mitigation measures MM BIO-3a—3d will in fact mitigate the Project's functional impacts to wetlands.

Ms. Corbin discusses several additional ways in which the DEIR fails to support the conclusion that the proposed wetland mitigation will actually be effective.

First, the DEIR lacks any evidence supporting the assumption that the proposed wetlands mitigation ratios will adequately mitigate the Project's significant impacts. The Project proposes to mitigate for Phase 1 and Phase 2 impacts at 2:1 and 1:1 ratios, respectively. Both the Devlin Road and Green Island Biological Assessments, prepared for the City in connection with projects adjacent to this Project Site and included in supporting materials for the DEIR, identify 2:1 as the typical Corps and Regional Water Quality Control Board required mitigation ratios.[202] The Corps identifies vernal pools as "difficult to replace resources" and "regionally significant habitat types," making vernal pool wetland creation an inherently high risk mitigation that warrants a higher than typical mitigation ratios.[203] The Corps also states that mitigation ratios greater than 1:1 are typically required because "mitigation sites often provide reduced functions compared to the impacted aquatic resources."[204] The DEIR offers no evidence supporting the assumption that these mitigation ratios, particularly the 1:1 ratio for Phase 2, will effectively mitigate lost wetland area and functions. 27

Second, the DEIR lacks evidence supporting that the proposed new wetlands area can be created and maintained. Ms. Corbin cites evidence demonstrating the difficulty of wetlands creation, especially with respect to vernal pools.[205] Successful

[205] *Id.*, pg. 6.

printed on recycled paper

wetland creation is "largely driven by ability to provide appropriate hydrology," i.e., it requires a source of water to create and maintain wetlands.[206] The DEIR does not provide any hydrologic analysis demonstrating wetland creation potential in the proposed mitigation area. Such analysis should include a water budget analysis, typically supported by hydrology monitoring in the proposed wetland creation area.[207] None of that analysis, crucial to assessing whether the proposed mitigation will be effective, is provided in the DEIR.

Finally, the wetland mitigation performance standards set forth in BIO MM 3-d will not ensure that such mitigation will be effective. This mitigation measure states that the basic objective of the Wetland Mitigation and Monitoring Plan is to "ensure that project wetland impacts, and compensatory mitigation proposed to offset the wetland impacts, shall provide a no-net-loss of area of wetlands, *and wetlands established/created shall be in-kind to the wetlands impacted* [emphasis added]."[208] As previously discussed, though, the DEIR provides no assessment of the impacted wetlands' functions. Nor is there a discussion of the impacted wetlands varied habitat conditions (e.g., isolated vs. non-isolated wetlands). Without an understanding of the impacted wetland functions, "there is no basis for establishing meaningful mitigation goals and associated meaningful performance standards to achieve no net loss."[209] By focusing on mitigation area size without replacing lost ecological function, the DEIR lacks any supporting evidence for its conclusion that the proposed wetland mitigation will be effective, and the plan does not comply with the State's no net loss policy.[210] 27

E. The DEIR Fails to Disclose, Analyze or Mitigate Biological Impacts.

1. **The DEIR Fails To Adequately Analyze And Mitigate Impacts To The Swainson's Hawk**. 28

Mr. Cashen discusses in detail how the DEIR fails to adequately disclose or mitigate significant impacts to Swainson's hawk, a California threatened species.[211] The DEIR fails to accurately describe the Project's significant impacts to Swainson's

[206] *Ibid.*

[211] Cashen Comments, pgs. 7-9, 14-15.

printed on recycled paper

hawk foraging habitat, the loss of which is one of the primary threats to the species in California.[212] The DEIR provides the following analysis of this issue:

> "Based upon the limited number of Swainson's hawk records within a 10-mile radius of the project site, there is sufficient foraging habitat in and within the vicinity of the project site. Based upon the limited number of known Swainson's hawk to occur within a 10 mile radius of the project site and the acreage of existing foraging habitat currently protected, the proposed project would not result in significant impacts to foraging habitat directly, indirectly, or cumulatively, therefore no mitigation is warranted for Swainson's hawk foraging habitat."[213]

Mr. Cashen identifies numerous flaws in this analysis.

First, while the DEIR asserts that the Project would "provide and preserve in perpetuity approximately 45 acres of open space that would include habitat currently suitable for foraging by the Swainson's hawk,"[214] it neglects to mention or analyze the fact that the Project will also result in the net *loss* of 163 acres of foraging habitat.[215] Moreover, the DEIR's discussion of habitat preservation fails to address that the Project will contain features (including landscaping and on-site drainage facilities) "designed and managed to discourage wildlife use of the site."[216] Nor does this discussion address mitigation measure MM LU-3, which would incorporate measures "to reduce the bird attractant potential of the wetland area, consistent with the [Airport Land Use Compatibility Plan] policies."[217] The DEIR's analysis of impacts to Swainson's hawk foraging habitat is incomplete without reconciling the attempts to preserve habitat with simultaneous efforts to discourage wildlife uses, and specifically bird uses, of the Project site. 28

Second, the DEIR fails to substantiate the assertion that there are only a "limited number" of Swainson's hawk records within a 10-mile radius of the Project site. Mr. Cashen provides evidence showing numerous records of Swainson's hawk in the vicinity of the Project site.[218]

printed on recycled paper

Third, the DEIR's biological survey to locate Swainson's hawk nests was limited to a single survey on April 16, 2021, during which the Applicant's biologist drove roads within one mile of the Project site to inspect trees for raptor nest structures.[219] This survey did not conform to Swainson's hawk survey protocol requiring at least three independent surveys between April 5 and April 20, and therefore provides incomplete baseline data.[220] As Mr. Cashen explains, following the protocol is crucial to locating Swainson's hawk nests, because the nests are often not visible from ground level and is only detectable when one of the birds flies to of from the nest site (i.e., through extensive "sit and watch" surveying).[221]

Fourth, the DEIR claims, without any supporting data or other evidence, that "there is sufficient foraging habitat in and within the vicinity of the project site." Mr. Cashen's analysis finds that "much of the open space that remains in the vicinity of the Project is comprised of vineyards, marshlands, or other land cover types that provide little to no value as foraging habitat for Swainson's hawk."[222] 28

In an attempt to reverse the decline of California's Swainson's hawk population, California Department of Fish & Wildlife's ("CDFW") policy is that new development projects that adversely modify nesting or foraging habitat within 10 miles of an active nest should provide compensatory mitigation.[223] Mr. Cashen cites evidence of active Swainson's hawk nests within 5 miles of the Project site,[224] which triggers the need for mitigation consistent with CDFW mitigation guidelines.[225]

Because the Project site is known to provide foraging habitat for Swainson's hawks and because the DEIR does not require compensatory mitigation for impacts to that habitat, the Project would have unmitigated significant impacts.

Unrelated to mitigation of impacts to Swainson's hawk foraging habitat, MM BIO-1 purports to establish pre-construction survey requirements to prevent potential construction-related impacts to Swainson's hawk nesting areas. This mitigation measure contains conflicting requirements and lacks substantial

printed on recycled paper

evidence demonstrating that it will be effective. MM BIO-1a states that preconstruction surveys "shall be completed for at least two survey periods immediately prior to commencement of project construction."[226] This is consistent with Swainson's hawk survey protocols which state that "[t]o meet the minimum level of protection for the species, surveys should be completed for at least the two survey periods immediately prior to a project's initiation."[227] However, MM BIO-1a goes on to state that "[i]f no nesting Swainson's hawk are found during the first non-optional survey period starting March 20, then project construction may commence."[228] Allowing construction to commence during the first non-optional survey period would violate the protocol and would not ensure protection of the species. 28

MM BIO-1a also requires a 1,000-foot buffer around any Swainson's hawk nesting sites. This conflicts with CDFW mitigation guidelines that call for a ¼ mile buffer.[229] The DEIR provides no evidence that a 1,000-foot buffer would be sufficient to prevent impacts, nor does it require monitoring to validate the adequacy of the reduced buffer.

For all the foregoing reasons, Project impacts on Swainson's hawks remain potentially significant and unmitigated, and the DEIR must be revised and recirculated to fully disclose, analyze and mitigate these impacts.

2. The DEIR Fails To Adequately Analyze And Mitigate Impacts To The Golden Eagle.

A golden eagle was observed foraging at the Project site during the wildlife survey for the HBC Report in support of the DEIR.[230] However, the DEIR offers no analysis of potential impacts of the Project to golden eagle foraging habitat. As discussed above, the Project will result in the net loss of more than 160 acres of potential foraging habitat, and will include features to discourage wildlife use and reduce bird attractant potential of the preserved open space. The DEIR fails to even acknowledge, let alone analyze or attempt to mitigate, Project impacts to golden eagle foraging habitat. 29

printed on recycled paper

The DEIR does consider the possibility that Project construction activities may disturb golden eagle nests and includes MM BIO-1b to mitigate these potential impacts. As Mr. Cashen points out, however, MM BIO-1b does not require pre-construction surveys that adhere to U.S. Fish and Wildlife Service ("USFWS") survey protocol, nor does it establish any standards for survey techniques or level of effort.[231] This matters because "golden eagle nests may be difficult to detect unless special techniques (e.g., aerial surveys) are implemented."[232] In addition, MM BIO-1b provides for a 1,000-foot buffer from any golden eagle nest, which is inconsistent with USFWS guidelines which recommend a one-mile no-disturbance buffer surrounding golden eagle nesting sites. As Mr. Cashen explains, golden eagles are known to be highly sensitive to many types of disturbance and may react to human activity as far as 1,500 meters (4,921 feet) from nesting sites.[233] While the species can develop tolerance to some forms of disturbance (e.g., hikers), there is no evidence that golden eagles can tolerate the high levels of disturbance that Project construction and operations would cause.[234] The DEIR provides no evidence that a 1,000-foot buffer would adequately mitigate impacts to golden eagles nesting near the Project site. 29

3. The DEIR Fails To Adequately Analyze And Mitigate Impacts To The Northern Harrier.

Northern harriers were observed foraging at the Project site during both winter and spring (breeding) seasons during surveys for the HBC Report and the DEIR recognizes that there is suitable nesting habitat throughout the Project site.[235] As with Swainson's hawk and golden eagle, the DEIR offers no analysis of the significance of up to 163 acres of habitat loss to the northern harrier, nor does it recognize the potential for lost breeding territory. As Mr. Cashen points out, the wetland preserve area would not mitigate such impacts as it does not provide suitable habitat for this species.[236] Northern harriers "require a mosaic of large undisturbed habitats for nesting and foraging" while the proposed wetlands 30

[236] Cashen Comments, pg. 10-11.

printed on recycled paper

preserve "would be a habitat 'island' subject to various forms of disturbance associated with the Project."[237] While MM BIO-1c attempts to mitigate direct harms to the northern harrier via pre-construction surveys and nest buffers, it does nothing to address potential loss of foraging and breeding habitat. Nor is there any evidence in the DEIR that the required 500-foot buffer zone around northern harrier nests would be sufficient to mitigate impacts. For these reasons, the Project's impacts on the northern harrier remain potentially significant and unmitigated. 30

4. The DEIR Fails To Analyze And Mitigate Impacts To The Merlin And Ferruginous Hawk.

The merlin and ferruginous hawk have been detected immediately north of the Project site[238] and the DEIR acknowledges that the Project site provides suitable foraging habitat for both species.[239] The Project would directly (via loss of 163 acres of undisturbed land) and functionally (via implementation of MM LU-3) eliminate habitat for these two species. The DEIR fails to disclose, analyze or incorporate mitigation for these potentially significant impacts. 31

5. The DEIR Fails To Adequately Mitigate Impacts To Breeding Birds (MM BIO-4).

The DEIR includes mitigation measure MM BIO-4, which requires a pre-construction breeding bird survey of the Project site and installation of "appropriate" buffer zones around all active nests. Mr. Cashen identifies three reasons why MM BIO-4 does not ensure that the Project's impacts to nesting birds will be mitigated to less than significant levels.[240] 32

First, MM BIO-4 fails to establish standards for: (a) nest searching techniques, (b) minimum level of effort (i.e., survey hours per unit area), and (c) qualifications of the biologist conducting the survey. As Mr. Cashen explains, the ability to successfully locate nests in the Project area is dependent on these three variables.

[237] *Ibid.*
[238] *Id.,* pg. 12.
[239] DEIR, Appendix C-1, Table 2.
[240] Cashen Comments, pgs. 18-20.

printed on recycled paper

While the Project site lacks trees, it provides potential habitat and nesting materials for ground-nesting birds.[241] Most ground-nesting birds construct nests that are inconspicuous and thus hard to find.[242] As a result, successfully locating nests of ground-nesting birds requires special techniques.[243] Because MM BIO-4 does not require implementation of such techniques, it provides no assurances that the Project would avoid take of nesting birds. In addition, locating all nests within the 200+ acres Project site may require a considerable level of effort. To ensure all bird nests that may be affected by the Project are located, the DEIR must establish standards for the survey effort (e.g., minimum number of survey hours per unit area). The success of any nest-searching method depends on the surveyor's knowledge of where birds nest, how nesting birds behave, and the best time of day to search for nests, knowledge which requires training and experience.[244] Because MM BIO-4 fails to establish standards for the "qualified biologist" that would conduct the nesting bird survey, it does not ensure the biologist would have the qualifications needed to successfully locate all nests within the Project area prior to construction. 32

Second, the DEIR fails to provide evidence that the buffer sizes proposed in MM BIO-4 would prevent negative impacts to nesting birds. Mr. Cashen opines that, based on his review of the literature, the 50-foot buffer proposed for passerines and other non-raptors is grossly deficient for almost all species. Construction noise levels associated with the Project may reach 90 dBA at a distance of 50 feet.[245] Noise at that level far exceeds the level that is deleterious to most breeding birds.[246] Consequently, a 50-foot buffer would be insufficient to avoid significant impacts to nesting birds. For other projects, the CDFW has recommended a minimum no-disturbance buffer of 500 feet for unlisted raptors and 250 feet for other non-listed bird species.[247]

Third, there are no performance standards, or monitoring and reporting requirements, for MM BIO-4. Monitoring is essential for two reasons: (1) to validate the adequacy of the nest buffers (and implement remedial actions if

[241] *Id.*, pg. 18.
[242] *Ibid.*
[243] *Id.*, pgs. 18-19.
[244] *Id.*, pg. 19. *See also* Martin TE, Geupel GR. 1993. Nest-Monitoring Plots: Methods for Locating Nests and Monitoring Success. J. Field Ornithol. 64(4):507-519.
[245] DEIR, p. 3.10-17.
[246] Cashen Comments, pg. 19.
[247] *Ibid.*

printed on recycled paper

necessary), and (2) to ensure construction workers comply with the nest buffers. Mr. Cashen states that, based on his experience, it is very difficult to ensure compliance with nest buffers unless a full-time biological monitor is present on site. 32

6. The DEIR's Mitigation Measures to Mitigate Wetlands Loss are Undermined by and in Conflict with MM LU-3.

As discussed, the DEIR fails to assess existing wetland functions (including habitat function) and therefore cannot demonstrate the efficacy of wetlands mitigation. However, any efforts to use the wetland preserve area to replace lost habitat functions will also be completely undermined by the application of a separate mitigation measure, MM LU-3.

Mitigation measure MM LU-3 seeks to address potential conflicts with the Napa County Airport Land Use Compatibility Plan ("ALUCP"). The ALUCP includes provisions seeking to avoid hazards to airplanes using the Napa County Airport, which is approximately 3,000 feet from the Project's proposed wetlands preserve area. Wetlands are attractive to many types of wildlife, including birds which can pose hazards to airplanes taking off and landing at nearby airports. As a result, the FAA recommends that wetland mitigation projects be sited at least 10,000 feet from the nearest aircraft operations area (for airports serving turbine-powered aircraft).[248] 33

To address this issue, MM LU-3 includes a provision requiring an assessment by a wildlife biologist of potential wildlife hazards to aviation. This assessment must "evaluate the characteristics of the emergent wetlands, drainages, other potential wildlife attractant features (i.e., ponded water) located within the open space area [i.e., the wetland preserve required by MM BIO-2 and BIO-3]."[249] MM LU-3 specifically requires that this assessment identify management practices to "prevent the creation of attractants for large flocks or [sic] birds or other wildlife species that may present safety hazards to aviation activities."[250] In discussing this measure, the DEIR notes that the Project will include "features that would be designed and managed to discourage wildlife use of the site."[251]

[248] Cashen Comments, pg. 14.
[249] DEIR, pg. 3.9-52.
[250] *Ibid.*
[251] *Ibid.*

printed on recycled paper

The DEIR fails to acknowledge the contradiction between, on the one hand attempting to mitigate the Project's significant impacts to wetlands by creating a wetland preserve, while on the other hand actively seeking to degrade the preserve as wildlife habitat. This conflict is yet another reason why the DEIR fails to establish that MM BIO-2 and MM BIO-3 will effectively mitigate the Project's wetlands impacts. Moreover, MM LU-3 may itself cause potentially significant impacts to wildlife, requiring that the DEIR separately disclose and analyze those impacts.[252] 33

7. The DEIR Fails To Adequately Analyze Or Mitigate Cumulative Impacts To Biological Resources.

CEQA requires that an EIR include consideration of cumulative impacts when a project's incremental effects are cumulatively considerable.[253] Among other requirements, the lead agency must define the geographical scope of the area affected by the cumulative effect and provide a reasonable explanation for the geographical limitation used.[254]

The DEIR states "[t]he geographical scope of the cumulative biological resources analysis is a 0.5-mile radius of the project site."[255] The DEIR provides no explanation for this 0.5-mile limitation, other than that the "project site is located at this transition between urban development and the marshes associated with the Napa River; accordingly, habitats in these areas tend to be disrupted and impacts would be localized."[256] The DEIR also states "[a]lthough there would be loss of foraging habitat, the cumulative loss of this resource would not be considerable due to the abundance of habitat in the American Canyon area." 34

There are several problems with the DEIR's analysis of cumulative impacts to biological resources. First, the DEIR fails to provide a reasonable explanation or any supporting evidence for limiting the geographical scope to 0.5 miles, offering only the conclusory statement that habitats in areas like the Project site "tend to be disrupted and impacts would be localized." Second, in finding that the loss of foraging habitat would not be cumulatively considerable, the DEIR relies on the "abundance of habitat in the American Canyon area." Again, there is no evidence

[252] 14 CCR § 15126.4(a)(1)(D).
[253] 14 CCR § 15130.
[254] 14 CCR § 15130(b)(3).
[255] DEIR, pg. 4-5.
[256] *Ibid.*

printed on recycled paper

for this assertion as the DEIR doesn't even attempt to describe where this abundant habitat is located, or what it is defining as the "American Canyon area." Nor does the DEIR attempt to square this assertion with the Biological Resources Analysis prepared for the City for the adjacent Green Island Road Widening Project, which states "the Giovannoni property is the only remaining, undisturbed habitat located in the vicinity of the project site."[257]

Furthermore, as Mr. Cashen points out, the DEIR's rationale is flawed as it applies two different geographic scales to the analysis. "It is not possible to accurately analyze cumulative impacts by using one geographic scale (i.e., the "American Canyon area") to analyze the abundance of remaining habitat, but a much smaller scale (i.e., 0.5-mile) to analyze other projects that would impact foraging habitat."[258] 34

VII. THE CITY MAY NOT MAKE THE REQUIRED FINDINGS TO APPROVE THE PROJECT'S LOCAL LAND USE PERMITS.

The Project requires that the City issue discretionary approvals, including a Use Permit and a Design Permit.[259] The Design Permit requires that the City make certain findings, including that the Project complies with all applicable General Plan policies.[260] The Use Permit requires that the City find that the Project is consistent with the policies and programs of the General Plan and will not be materially detrimental to the general health, safety and welfare of the public and residents in the vicinity of the Project.[261] As discussed above, the DEIR fails to disclose, analyze or effectively mitigate the Project's potentially significant impacts on air quality, public health, biological resources and transportation. These impacts also create inconsistencies with the General Plan polices which the DEIR fails to disclose and mitigate. As a result of these inconsistencies, the City is unable to make the necessary findings to approve the Project's local land use permits. 35

As an initial matter, the City may not make the required finding, pursuant to Municipal Code section 19.42.202 D.5., that the Project will not be materially detrimental to the general health, safety or general welfare of the public and residents in the vicinity of the Project. As discussed above, the Health Risk

[257] DEIR, Appendix C.7, pg. 8.

[261] American Canyon Municipal Code § 19.42.020 D.1 and D.5.

printed on recycled paper

Assessment performed for the Project has serious flaws which prevent it from adequately analyzing health risks to sensitive receptors from the Project's air emissions. 35a

The City is also precluded from making required findings pursuant to Municipal Code sections 19.41.050 C (for issuance of a Design Permit) and 19.42.020 D.1 (for issuance of a Conditional Use Permit) because it cannot find that the Project complies with and is consistent with applicable General Plan policies. Our analysis of the DEIR reflected in these comments show that the Project fails to comply with several key policies in the General Plan, including the following.

(a) Circulation Element. Guiding Policy 1.11 calls for the reduction of total vehicle miles traveled by City residents, and Policy 1.24 states that new development will be responsible for mitigation of transportation impacts. As explained in detail above, the DEIR's VMT analysis is completely unsupported and does not demonstrate that the Project will reduce VMT as compared to existing averages. To the contrary, transportation expert Norm Marshall provided evidence showing that the Project's VMT is likely to exceed applicable existing averages and therefore requires mitigation. Because the Project will not reduce VMT and will not mitigate potentially significant traffic impacts, the City cannot make the required finding of consistency with the General Plan's Circulation Element. 35b

(b) Natural and Historic/Cultural Resources Element. The General Plan includes several applicable policies with respect to the Project's impacts to biological resources.

- Policy 8.21 provides that land use applications for developments located within sensitive habitats, including riparian habitats or habitats within areas occupied by vernal pools, shall be accompanied by sufficient technical background data to enable an adequate assessment of the potential for impacts on these resources and possible measures to reduce any identifiable impacts. As discussed herein, the DEIR lacks sufficient technical background data to assess impacts to wetlands or to mitigate such impacts because it lacks any lacks any functional assessment of the existing wetlands on the Project site. Moreover, the DEIR completely fails to examine the Project's impacts on foraging habit for several special status bird species. 35c
- Policy 8.31 requires that for developments in wetlands and riparian habitats, retained riparian corridors "shall be protected by an adequate 35d

printed on recycled paper

buffer with a minimum 100 foot protection zone…" The Project's proposed buffer zones associated with No-Name Creek and the associated wetlands are not discussed in the DEIR or supporting technical documents, nor are they labeled in figures. Using the figure scales strongly suggests that buffer widths adjacent to Project development will be less than 100 feet in many places.[262] 35d

- Policy 8.41 requires that development plans incorporate all reasonable mitigation measures to avoid significantly impacting vernal pools. As discussed herein, the DEIR's lack of a functional assessment of the Project site's wetlands, including vernal pools, makes it impossible to evaluate the efficacy of the proposed mitigation measures. 35e
- Policy 8.42 requires preservation, where possible, of the habitat of rare, threatened or endangered species, specifically including the northern harrier and golden eagle. Both of those species have been observed foraging at the Project site, and as discussed in detail above, the DEIR fails to evaluate the loss of foraging habitat, let alone make any efforts to preserve such habitat. 35f
- Policy 8.43 encourages activities that improve the biological value and integrity of the City's natural resources through, *inter alia,* control of alien plants. The Project has the potential to introduce invasive plant species and to facilitate their spread.[263] Construction vehicles and equipment are common vectors for transporting invasive plant seeds or spores from one place to another, and soil and vegetation disturbance associated with construction creates suitable conditions for establishment of invasive plants.[264] The DEIR fails to include any mitigation to minimize the Project's potential to introduce invasive plant species or facilitate their spread. 35g

The DEIR fails to address or remedy these inconsistencies with General Plan policies, and the City accordingly may not make the necessary findings to support the required discretionary approvals for the Project.

VIII. CONCLUSION

For the reasons discussed above, the DEIR for the Project is wholly inadequate under CEQA. It must be thoroughly revised to provide legally adequate 36

[262] Corbin Comments, pg. 8.
[263] Cashen Comments, pg. 12.
[264] *Ibid.*

printed on recycled paper

analysis of, and mitigation for, all of the Project's potentially significant impacts. These revisions will necessarily require that the DEIR be recirculated for additional public review. Until the DEIR has been revised and recirculated, as described herein, the County may not lawfully approve the Project. 36

Thank you for your attention to these comments. Please include them in the record of proceedings for the Project.

Sincerely,

Richard M. Franco

Adams Broadwell Joseph & Cardozo
601 Gateway Boulevard, Suite 1000
South San Francisco, CA 94080

Attn: Mr. Richard Franco

Subject: Comments On Draft Environmental Impact Report (DEIR) For Giovanonni Logistics Center Project, City of American Canyon, Napa County, California, State Clearinghouse Number 2021010104

Dear Mr. Franco:

At the request of Adams Broadwell Joseph & Cardozo (ABJC), Clark and Associates (Clark) has reviewed materials related to the 2022 City of American Canyon's (the City's) DEIR of the above referenced project. 1

Clark's review of the materials in no way constitutes a validation of the conclusions or materials contained within the plan. If we do not comment on a specific item this does not constitute acceptance of the item.

Project Description:

According to the City the proposed project consists of the development of up to 2.4 million square feet of high-cube warehouse on 163 acres of the project site. Phase 1 consists of approximately 1.1 million square feet on the eastern portion of the project site. Phase 2 consist of approximately 1.3 million square feet on the western portion of the project site. Approximately 45 acres of the project site would be preserved as wetlands. The applicant would extend the Napa Valley Vine Trail along the project frontage with Devlin Road and Green Island Road. 2

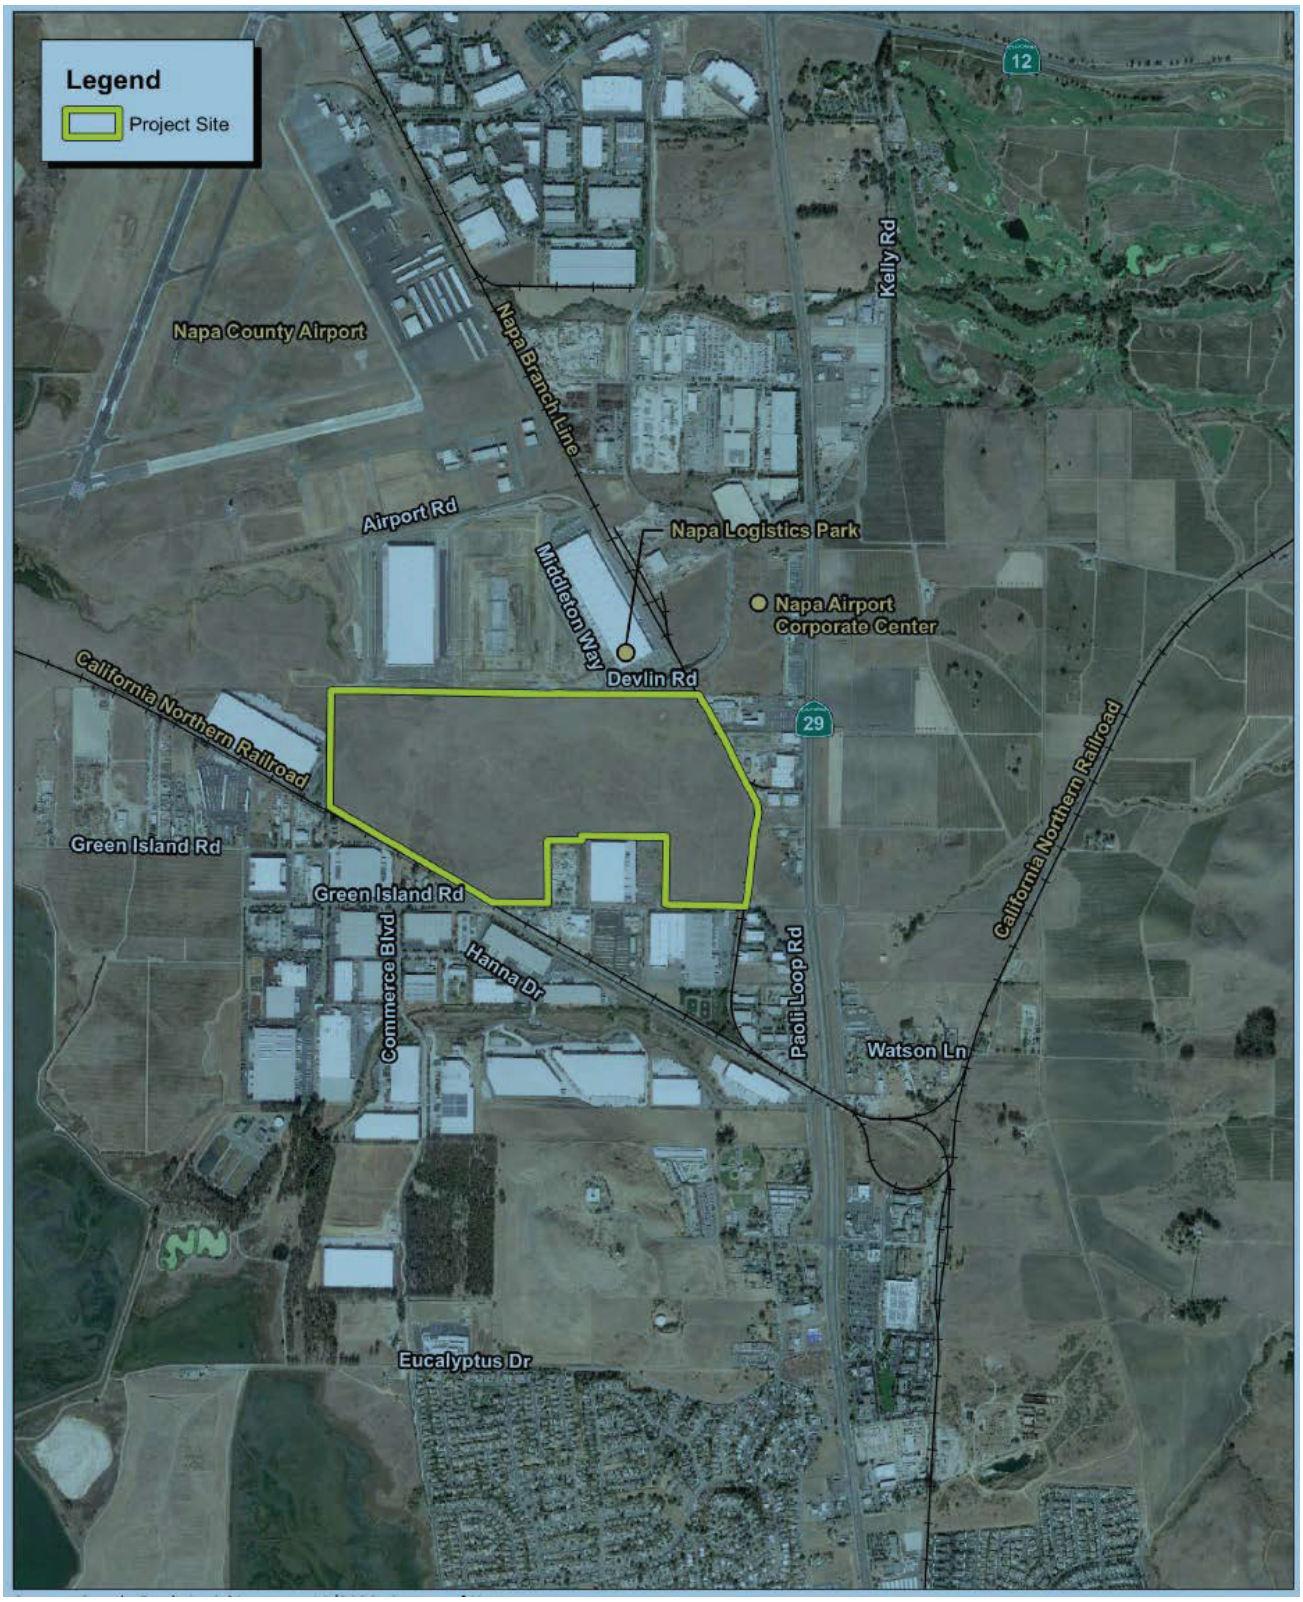

Figure 1: Project Site Location

Unavoidable Significant Impacts

According to the City's DEIR of the Project, the potentially significant and unavoidable impacts from the project include:

- Consistency With Air Quality Management Plan: The proposed project would result in exceedances of regional emissions thresholds and, therefore, be inconsistent with the Bay Area Air Quality Management District (BAAQMD) regional air quality planning assumptions. Mitigation is proposed requiring the implementation of feasible emissions reduction measures; however, these measures would not reconcile this inconsistency. Therefore, the significance after mitigation is significant and unavoidable.
- Cumulative Criteria Pollutant Emissions Impacts: The proposed project would result in a cumulatively considerable net increase of criteria pollutants for which the project region is nonattainment under an applicable federal or State ambient air quality standard. Mitigation is proposed requiring the implementation of air emissions reduction measures, but it would not fully reduce this impact to a level of less than significant. Therefore, the significance after mitigation is significant and unavoidable.

3

The conclusion from the City that the significant impacts are unavoidable is not supported by the facts of the Project. There are substantial impacts that are not addressed in the City's analysis, as well as numerous feasible mitigation measures that the City fails to consider, that must be addressed in a revised environmental draft impact report (R-DEIR).

Specific Comments:

1. The Air Dispersion Model Used For The Health Risk Assessment For Operational Phases Of The Project Has A Structural Flaw That Result In Inaccurate Estimates Of The Project Emissions Within The Community

4

The modeling approach has a significant flaw - the model does not account for the impact on emissions from building downwash. If the building downwash were included in the model, then the Proponent would be reasonably expected to call that out in the text summary of the model. The AERMOD model calculates the ground-level concentration of DPM emission associated with the

project. The height of release for emissions from idling trucks is generally assumed to be 2.55 meters to 3.4 meters (8.4 feet to 11.2 feet) well below the height of the building. The release height for DPM from trucks traveling along the streets is generally assumed to be at the ground surface (0 meters or 0 feet).

Building downwash occurs as the wind flows over and around buildings and impacts the dispersion of pollution from nearby stacks. A plume caught in the path of this flow is drawn into the wake, temporarily trapping it in a recirculating cavity. This downwash effect leads to higher ground-level concentration of chemicals emitted from sources. The downwash effect increases as the relative difference between the release height and top of the building increases.[1] For the closest receptors to the site, the residences to the east of the Project, this difference will create an additional air quality impact that is not accounted for in the City's analysis. Guidance from authoritative bodies in California regarding the preparation of health risk assessments of mobile sources of diesel emissions[2] requires the inclusion of building heights and dimensions for building downwash calculations. Omission of the building downwash effect underestimates the exposure point concentrations for receptors near the building(s). The City should address the impact of this issue in a R-DEIR. 4

2. The City Has Failed To Quantify All Of The Health Impacts Emissions From The Project On The Surrounding Community.

The City must assess the air quality impacts for all toxic air compounds (TACs) that will be released during the construction and operational phases of the project. CARB[3] defines diesel exhaust as a complex mixture of inorganic and organic compounds that exists in gaseous, liquid, and solid phases. CARB and U.S. EPA identify 40 components of the exhaust as suspected human carcinogens, 5

[1] The so-called good engineering practice height (GEP) of the source. The GEP is defined in Section 123 of the Clean Air Act as "the height necessary to ensure that emissions from a stack do not result in excessive concentrations of any air pollutant in the immediate vicinity of the source as a result of atmospheric downwash, eddies or wakes which may be created by the source itself, nearby structures or nearby terrain obstacles."

[2] SCAQMD. 2003. Health Risk Assessment Guidance For Analyzing Cancer Risks From Mobile Source Diesel Emissions. August, 2003. Page 2.

[3] CARB. 1998. Report to the Air Resources Board on the Proposed Identification of Diesel Exhaust as a Toxic Air Contaminant, Part A, Public Exposure To, Sources and Emissions of Diesel Exhaust In California. April 22, 1998. Pg A-1.

including formaldehyde, 1,3-butadiene, and benzo[a]pyrene. The inhalation unit risk factor identified by OEHHA for use in risk assessments is for the particulate matter (DPM) fraction of diesel exhaust and not the vapor phase components identified by CARB and U.S. EPA.

There is notable precedent requiring a quantitative analysis of TACs from diesel exhaust in CEQA documents. Moreover, the absence of this analysis renders the DEIR's health risk analysis incomplete. In a 2017 Air Quality Technical Report[4] submitted in support of a Draft EIR for the Turk Island Landfill Consolidation and Residential Subdivision[5], proponents accounted for the gaseous phase of diesel emission and detailed the speciated diesel total organic gas (TOG) emissions along with the DPM emissions for all construction equipment. The speciated diesel TOG emissions and DPM emissions were utilized in dispersion modeling to identify the maximally exposed individual sensitive receptor (MEISR) of the project to determine the health risks associated with all sources of air toxins from the construction phase of the project. This is a common and feasible analysis that is routinely performed for development projects like the Giovanonni Logistics Center Project. . 5

Here, the City's analysis ignores the presence of TACs being emitted with diesel exhaust during the construction and operational phases of the project without making any attempt to quantify the impacts. This omission is a continuing flaw that must be addressed by the City. The results should then be presented in an REIR prior to approving any agreements with the Proponent or issuing any permits for the Project.

3. Mitigation Measure AQ-2d Assumes That The Fleet of Heavy Duty Trucks Entering the Site Will Be From Year 2014 Or Later. If the MM Can Require A Specific Age of Vehicles Entering The Project Site, It Should Be Changed To Make A Real Impact On Emissions From The Heavy Duty Truck Traffic. 6

The City's MM requires heavy-duty vehicles entering or operation on the Phase I project

[4] Ramboll Environ. 2017. Air Quality Technical Report Turk Island Landfill Consolidation And Residential Subdivision Project. Prepared For City of Union City, Union City, CA. Prepared by Ramboll Envion US Corporation, San Francisco, CA August, 2017. https://www.unioncity.org/DocumentCenter/View/1867/Turk-Island---App-D---AQ-Emissions-Report?bidId=

[5] Union City. 2018. Draft Environmental Impact Report (DEIR) Turk Island Landfill Consolidation And Residential Subdivision Project. SCH Number 20008112107. Dated 3/15/2018. https://www.unioncity.org/DocumentCenter/View/1863/Turk-Island-DEIR?bidId=

site be model year 2014 or later. The City proffers that model year 2014 was selected as the baseline for MM AIR-2d since it is the first homogenous model year for a trucking fleet in Napa County to demonstrate a reduction in NOx emissions when compared with unmitigated emission estimates.[6] The DEIR goes on to state that this would allow the proposed project to utilize trucks which are 9 years old and would not constitute an infeasible financial burden. No explanation is provided as to why a 9 year age value is important in deciding how mitigation is best achieved in this measured. If the City can arbitrarily limit the age of the heavy duty vehicles entering and exiting the site in the mitigation measure, then clearly choosing newer model vehicles will limit the impacts of the Project on the surrounding community.

Using the California Air Resources Board's (CARB) EMission FACtor (EMFAC) model, it is possible to estimates the emissions from onroad mobile sources in California, including but not limited to heavy duty trucks. The model calculates emissions factors and emissions inventories for:

- Carbon monoxide (CO)
- Nitrogen oxides (NOx)
- Hydrocarbons (HC): HC can be expressed as TOG (total organic gases), ROG (reactive organic gases), THC (total hydrocarbon), or CH_4 (methane). The TOG class includes all organic gases emitted into the atmosphere. The ROG class is same as EPA's VOC (volatile organic compounds) definition and does not contain compounds exempt from regulation.
- Particulate matter (PM): PM estimates are provided for total suspended particulates for particulate matters 10 microns or less in diameter (PM_{10}), and particulate matters 2.5 microns or less in diameter ($PM_{2.5}$).
- Sulfur oxides (SO_x): Emissions of oxides of sulfur are a function of the sulfur content of fuel. The model calculates these emissions by multiplying the fuel consumption by the weight fraction of sulfur in a gallon of fuel.
- Greenhouse Gases (GHG): GHG emissions are consisted of complete combustion CO_2, Nitrous Oxide (N_2O) and Methane (CH_4). These are the greenhouse gases that are now included in the EMFAC2017 but not in EMFAC2014 or prior versions

6

In my analysis the emissions for NO_x, $PM_{2.5}$ as exhaust, and ROGs for vehicles with model years 2014

[6] DEIR. 2022. Pg 3.2-52

through 2023 are presented in the table below.

6

Note: Units: g/mile for RUNEX, g/vehicle/day for IDLEX

Based on the averaged emissions from the table above it is clear that changing the minimum allowable model year from 2014 to 2018 would result in:

- A 31% reduction in running NO_x emissions (NO_x RUNEX) from trucks operating on site.
- A 19.5% reduction in diesel particulate matter (DPM) emissions from trucks measured as particulate matter less than 2.5 microns ($PM_{2.5}$) operating on site ($PM_{2.5}$ RUNEX).
- A 17% reduction in reactive organic gases (ROGs) from trucks operating on site (ROG RUNEX).

6

Based on the averaged emissions from the table above it is clear that changing the minimum allowable model year from 2014 to 2020 would result in:

- A 41% reduction in NO_x emissions from trucks operating on site.
- A 39% reduction in diesel particulate matter (DPM) emissions from trucks measured as particulate matter less than 2.5 microns ($PM_{2.5}$) operating on site.
- A 26% reduction in reactive organic gases (ROGs) from trucks operating on site.

4. There Are A Number Of Mitigation Measures That Will Have A Direct Impact On Operational NOx and GHG Emissions Not Explored By The City In The DEIR

Mitigation measures that have previously been recommended by the California Air Resources Board and the Air Quality Management Districts in California to reduce operational NO_x and GHG emissions not included in the DEIR by the City include:

1. Include contractual language in tenant lease agreements that requires tenants to use the cleanest technologies available, and to provide the necessary infrastructure to support zero-emission vehicles and equipment that will be operating on site.
2. Include contractual language in tenant lease agreements that requires all TRUs entering the project site be plug-in capable.
3. Include contractual language in tenant lease agreements that requires future tenants to exclusively use zero-emission light and medium-duty delivery trucks and vans.
4. Include contractual language in tenant lease agreements requiring all TRUs, trucks, and cars entering the Project site be zero-emission.

7

5. Include contractual language in tenant lease agreements that requires all heavy-duty trucks entering or on the project site to be model year 2019 or later, expedite a transition to zero-emission vehicles, and be fully zero-emission beginning in 2030.
6. Include contractual language in tenant lease agreements that requires the tenant be in, and monitor compliance with, all current air quality regulations for on-road trucks including CARB's Heavy-Duty (Tractor-Trailer) Greenhouse Gas Regulation,[7] Periodic Smoke Inspection Program (PSIP),[8] and the Statewide Truck and Bus Regulation.[9]
7. Include contractual language in tenant lease agreements restricting trucks and support equipment from idling longer than five minutes while on site.
8. Include rooftop solar panels for each proposed warehouse to the extent feasible, with a capacity that matches the maximum allowed for distributed solar connections to the grid.
9. Have truck routes clearly marked with trailblazer signs, so that trucks will not enter residential areas.
10. Limit the daily number of trucks allowed at the Proposed Project to levels analyzed in the CEQA document. If higher daily truck volumes are anticipated to visit the site, the City as the Lead Agency should commit to re-evaluating the Proposed Project through CEQA prior to allowing this land use or higher activity level.
11. Ensure that any check-in point for trucks is well inside the Proposed Project site to ensure that there are no trucks queuing outside of the facility.
12. Establish overnight parking within the industrial building where trucks can rest overnight.
13. Establish area(s) within the Proposed Project site for repair needs.

7

[7] In December 2008, CARB adopted a regulation to reduce greenhouse gas emissions by improving the fuel efficiency of heavy-duty tractors that pull 53-foot or longer box-type trailers. The regulation applies primarily to owners of 53-foot or longer box-type trailers, including both dry-van and refrigerated-van trailers, and owners of the heavy-duty tractors that pull them on California highways. CARB's Heavy-Duty (Tractor-Trailer) Greenhouse Gas Regulation is available at: https://www.arb.ca.gov/cc/hdghg/hdghg.htm.

[8] The PSIP program requires that diesel and bus fleet owners conduct annual smoke opacity inspections of their vehicles and repair those with excessive smoke emissions to ensure compliance. CARB's PSIP program is available at: https://www.arb.ca.gov/enf/hdvip/hdvip.htm.

[9] The regulation requires that newer heavier trucks and buses must meet particulate matter filter requirements beginning January 1, 2012. Lighter and older heavier trucks must be replaced starting January 1, 2015. By January 1, 2023, nearly all trucks and buses will need to have 201 0 model year engines or equivalent. CARB's Statewide Truck and Bus Regulation is available at: https://www.arb.ca.gov/msprog/onrdiesel/onrdiesel.htm

5. The HRA Failed To Accurately Account For The Back-up Generator (BUG) Usage Onsite. The HRA Accounts For 50 Hours Of Operation And Does Not Account For The More Likely Use of Up To 200 Hours Of Operation Per Year.

The three 50 horse power (hp) BUGs were assumed to be operated up to 48 hours per year. Under the California Air Resources Board (CARB) Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines[10] guidance, the District may allow a new stationary emergency standby diesel-fueled Cl engine (> 50 hp) to operate up to 100 hours per year for *maintenance and testing purposes* on a site-specific basis, provided the diesel PM emission rate is less than or equal to 0.01 g/bhp-hr. In addition to the testing emissions, the air quality analysis in the DEIR must include the substantial increase in operational emissions from BUGs in the Air Basin due to unscheduled events, including but not limited to Public Safety Power Shutoff (PSPS) events and extreme heat events. Extreme heat events are defined as periods where in the temperatures throughout California exceed 100 degrees Fahrenheit. The total duration of the PSPS events lasted between 141 hours to 154 hours in 2019. In 2021, the Governor of California declared that during extreme heat events the use of stationary generators shall be deemed an emergency use under California Code of Regulations (CCR), title 17, section 93115.4 sub. (a) (30) (A)(2). The number of Extreme Heat Events is likely to increase in California with the continuing change in climate the State is currently undergoing. Coupling the testing time (50 hours per year) with the use during PSPS events (approximately 150 hours per year), it is more likely that the BUG will be operated at least 200 hours per year. 8

Power produced during PSPS or extreme heat events is expected to come from engines regulated by CARB and California's 35 air pollution control and air quality management districts (air districts). Of particular concern are health effects related to emissions from diesel back-up engines. DPM has been identified as a toxic air contaminant, composed of carbon particles and numerous organic compounds, including over forty known cancer-causing organic substances. The majority of DPM is small enough to be inhaled deep into the lungs and make them more susceptible to injury.

[10] Title 17, California Code of Regulations section 93115

According to the California Public Utilities Commission (CPUC) de-energization report in October 2019, there were almost 806 PSPS events (emphasis added) that impacted almost 973,000 customers (~7.5% of households in California) of which ~854,000 of them were residential customers, and the rest were commercial/industrial/medical baseline/other customers. CARB's data also indicated that on average each of these customers had about 43 hours of power outage in October 2019. Using the actual emission factors for each diesel BUG engines in the air district's stationary BUGs database, CARB staff calculated that the 1,810 additional stationary generators (like those proposed for the Project) running during a PSPS in October 2019 generated 126 tons of NOx, 8.3 tons or particulate matter, and 8.3 tons of DPM. 8

For every PSPS or Extreme Heat Event (EHE) triggered during the operational phase of the project, significant concentrations of DPM will be released. A R-DEIR should be prepared for the Project that includes an analysis of the additional operation of the BUG that will occur at the project site that is not accounted for in the current air quality and GHG analyses.

Conclusion

The facts identified and referenced in this comment letter lead me to reasonably conclude that the Project could result in significant unmitigated impacts if the DEIR is approved. The City must re-evaluate the significant impacts identified in this letter by requiring the preparation of a revised draft environmental impact report. 9

Sincerely,

James J. J. Clark, Ph.D.

Principal Toxicologist

Toxicology/Exposure Assessment Modeling

Risk Assessment/Analysis/Dispersion Modeling

Education:

Ph.D., Environmental Health Science, University of California, 1995

M.S., Environmental Health Science, University of California, 1993

B.S., Biophysical and Biochemical Sciences, University of Houston, 1987

Professional Experience:

Dr. Clark is a well-recognized toxicologist, air modeler, and health scientist. He has 30 years of experience in researching the effects of environmental contaminants on human health including environmental fate and transport modeling (SCREEN3, AEROMOD, ISCST3, Johnson-Ettinger Vapor Intrusion Modeling, RESRAD, GENII); exposure assessment modeling (partitioning of contaminants in the environment as well as PBPK modeling); conducting and managing human health risk assessments for regulatory compliance and risk-based clean-up levels; and toxicological and medical literature research.

SELECTED AIR MODELING RESEARCH/PROJECTS

Client(s) - Confidential

Dr. Clark performed a historical dose reconstruction for community members from an active 700 acre petroleum refinery in Los Angeles. The analysis included a multi-year dispersion model was performed in general accordance with the methods outlined by the U.S. EPA and the SCAQMD for assessing the health impacts in Torrance, California. The results of the analysis are being used as the basis for injunctive relief for the communities surrounding the refinery.

Client(s) – Multiple

Indoor Air Evaluations, California: Performed multiple indoor air screening evaluations and risk characterizations consistent with California Environmental Protection Agency's (Cal/EPA) Department of Toxic Substances Control (DTSC) and Regional Water Quality Control Board (RWQCB) methodologies. Characterizations included the use of DTSC's

10

modified Johnson & Ettinger Model and USEPA models, as well as the attenuation factor model currently advocated by Cal/EPA's Office of Environmental Health and Hazard Assessment (OEHHA).

Client – Adams, Broadwell, Joseph Cardozo, P.C.

Dr. Clark has performed numerous air quality analyses and risk assessments of criteria pollutants, air toxins, and particulate matter emissions for sites undergoing evaluation via the California Environmental Quality Act (CEQA) process. The analyses include the evaluation of Initial Study (IS) and Environmental Impacts Reports (EIR) for each project to determine the significance of air quality, green house gas (GHG), and hazardous waste components of the projects. The analyses were compiled as comment letters for submittal to oversight agencies.

Client – Confidential

Dr. Clark performed a comprehensive evaluation of criteria pollutants, air toxins, and particulate matter emissions from a carbon black production facility to determine the impacts on the surrounding communities. The results of the dispersion model were used to estimate acute and chronic exposure concentrations to multiple contaminants and were be incorporated into a comprehensive risk evaluation.

Client – Confidential

Dr. Clark performed a comprehensive evaluation of air toxins and particulate matter emissions from a railroad tie manufacturing facility to determine the impacts on the surrounding communities. The results of the dispersion model have been used to estimate acute and chronic exposure concentrations to multiple contaminants and have been incorporated into a comprehensive risk evaluation.

PUBLIC HEALTH/TOXICOLOGY

Client: Confidential

Dr. Clark performed a historical dose reconstruction for community members from radiologically impacted material (RIM) releases from an adjacent landfill. The analysis was performed in general accordance with the methods outlined by the Agency for Toxic Substances Control (ATSDR) for assessing radiation doses from historical source areas in North St. Louis County, Missouri.

Client: City of Santa Clarita, Santa Clarita, California

Dr. Clark managed the oversight of the characterization, remediation and development activities of a former 1,000 acre munitions manufacturing facility for the City of Santa

Clarita. The site is impacted with a number of contaminants including perchlorate, unexploded ordinance, and volatile organic compounds (VOCs). The site is currently under a number of regulatory consent orders, including an Immanent and Substantial Endangerment Order. Dr. Clark assisted the impacted municipality with the development of remediation strategies, interaction with the responsible parties and stakeholders, as well as interfacing with the regulatory agency responsible for oversight of the site cleanup.

Client: Confidential

Dr. Clark performed a historical dose reconstruction for community members exposed to radioactive waste released into the environment from legacy storage facilities. The releases resulted in impacts to soils, sediments, surface waters, and groundwater in the vicinity of the sites. The analysis was performed in general accordance with the methods outlined by the Agency for Toxic Substances Control (ATSDR) for assessing radiation doses from historical source areas in the community.

Client: Confidential

Dr. Clark performed a dose assessment of an individual occupationally exposed to metals and silica from fly ash who later developed cancer. A review of the individual's medical and occupational history was performed to prepare opinions regarding his exposure and later development of cancer.

Client: Brayton Purcell, Novato, California

Dr. Clark performed a toxicological assessment of residents exposed to methyl-tertiary butyl ether (MTBE) from leaking underground storage tanks (LUSTs) adjacent to the subject property. The symptomology of residents and guests of the subject property were evaluated against the known outcomes in published literature to exposure to MTBE. The study found that residents had been exposed to MTBE in their drinking water; that concentrations of MTBE detected at the site were above regulatory guidelines; and, that the symptoms and outcomes expressed by residents and guests were consistent with symptoms and outcomes documented in published literature.

Client: Confidential

Dr. Clark performed a toxicological assessment of an individual occupationally exposed to hexavalent chromium who later developed cancer. A review of the individual's medical and occupational history was performed to prepare opinions regarding her exposure and later development of cancer.

Client: Covanta Energy, Westwood, California

Evaluated health risk from metals in biosolids applied as soil amendment on agricultural lands. The biosolids were created at a forest waste cogeneration facility using 96% whole tree wood chips and 4 percent green waste. Mass loading calculations were used to estimate Cr(VI) concentrations in agricultural soils based on a maximum loading rate of 40 tons of biomass per acre of agricultural soil. The results of the study were used by the Regulatory agency to determine that the application of biosolids did not constitute a health risk to workers applying the biosolids or to residences near the agricultural lands.

Client: Kaiser Venture Incorporated, Fontana, California

Prepared PBPK assessment of lead risk of receptors at a 1,100-acre former steel mill. This evaluation was used as the basis for granting closure of the site by lead regulatory agency.

RISK ASSESSMENTS/REMEDIAL INVESTIGATIONS

Kaiser Ventures Incorporated, Fontana, California
